Prescriptivism is a theory about moral statements. It claims that such statements contain an element of meaning which serves to prescribe or direct actions. The history of prescriptivism includes Socrates, Aristotle, Hume, Kant and Mill, and it has been influential also in recent times.

Moral statements also contain a factual or descriptive element. The descriptive element of morality differs between persons and cultures, but the prescriptive element remains constant.

Prescriptivism can allow for moral disagreement, and explain moral weakness. It can also explain better than other theories the rationality and objectivity of moral thinking.

1 Definition and history

Prescriptivism is a meta-ethical theory about the meaning of moral statements which holds that, in addition to any factual or descriptive meaning they may have, there is a prescriptive element in their meaning which is irreducible to any factual equivalent, but serves to prescribe or direct actions (see Analytic ethics §1; Moral judgment §1).

The prescriptivity of moral statements has been recognized from the earliest times by philosophers, though it is only in the present century that thinkers have begun to develop a clear account of the relation between the descriptive and prescriptive elements in their meaning. Socrates was in part a prescriptivist, as is evident from the trouble he had in explaining how one could think something good, and yet not pursue it (see especially Plato's *Protagoras* (358) and *Gorgias* (467)) (see Socrates §6). Aristotle, who took up Socrates' problem about weakness of will, showed clearly, by his handling of it, a prescriptivist strand in his theory (*Nicomachean Ethics* 1145b23) (see Akrasia). *Phronēsis* or practical wisdom, which tells us what we ought to do, is described by him as *epitāktikē* or prescriptive (*Nicomachean Ethics* 1143a8) (see Aristotle §23). The practical syllogisms which are the channel of this instruction all have prescriptive first premises (*Nicomachean Ethics* 1144a31, 1147a25; *On the Soul* 434a16; *On the Movement of Animals* 701a7); if they did not, they could not validly conclude in actions. He solved Socrates' problem in a way consistent with his prescriptivism (see Hare 1992a).

Hume also recognized the prescriptive element in the meaning of moral statements (see especially *A Treatise of Human Nature* (1739-40), where he wrongly claims that because of its lack of prescriptivity 'reason is perfectly inert') (see Hume, D. §4, 8); but his settled theory was subjectivist rather than prescriptivist (the two kinds of theory are to this day often confused). He says that 'when you pronounce an action or character to be vicious, you mean nothing, but that from the constitution of your nature you have a feeling or sentiment of blame from the contemplation of it' (1739-40). Moral statements are for him reports rather than expressions of feelings or desires.

Kant rescued reason from inertia, and was clearly a prescriptivist; moral facts play no significant part in his ethical theory, the basic constituents of which are maxims, that is to say, prescriptions, originating in the will, and expressed often in the imperative (the German *soll* is equivalent to an imperative) (see Kantian ethics). Echoing the language of Hume about 'is' and 'ought', J.S. Mill avowedly declared himself a prescriptivist by calling moral statements 'imperatives' (1843) (see Mill, J.S. §11). But modern descriptivist opponents of prescriptivism, who often have a blind spot for prescriptivity, have seldom noticed these premonitions of modern prescriptivism.

In recent times many philosophers have held prescriptivist views of more or less considered kinds (such as Carnap 1935: 18; Ayer 1936, 1949; Stevenson 1944) (see Ayer, A.J. §5; Carnap, R. §3; Stevenson, C.L.). These were all followers of emotivism, the view that moral statements get their meaning by expressing feelings or attitudes of approval or disapproval (see Emotivism). But prescriptivists do not have to be emotivists; if they are concerned for the rationality of moral thinking they will not be. It is possible to hold, with Kant, that moral maxims originate in the rational will, which he says 'is nothing but practical reason' ([1785] 1903: 412), and that, though their main function is not to state facts, the adoption of them can be a rational process. A recent version of prescriptivism put forward by R.M. Hare has, following Kant, claimed objectivity, in a sense carefully defined and distinguished from factuality, for moral statements (see Hare 1993).

2 Prescriptive and descriptive meaning

Prescriptive meaning is often likened generically to that of imperatives, which also prescribe actions; but careful

ethical prescriptivists emphasize also the differences, as well as the similarities, between moral statements and imperatives. The chief of these differences is that moral statements also have, unlike imperatives, a descriptive or factual content. This is linked with another feature of moral statements, known in the jargon as universalizability: the feature that a moral statement about one situation must apply to any other situation similar in all its universal properties (that is, those which can be described without reference to the individuals involved). That moral statements are universalizable is acknowledged by most thinkers, whether or not they are prescriptivists (see Universalism in ethics).

If moral statements are universalizable in this way, they will inevitably acquire a descriptive function as part of their meaning; for someone who makes such a statement must think that the moral properties of the situation about which it is made supervene on its nonmoral properties (the reasons for making it) in accordance with a principle applying to all identically similar situations (see Supervenience). Thus they will be taken to hold that there are facts that justify the statement, and it thus acquires a factual, descriptive content or meaning. However, since different people and cultures hold differing moral principles, this descriptive meaning (the truth conditions of the statement) may vary from one person or culture to another (see Moral relativism). It is the prescriptive meaning which remains constant: whatever kinds of behaviour different people or cultures prescribe, they are all prescribing them for all similar cases. This, as we shall see, is what gives moral reasoning its grip.

The relation between the prescriptive and descriptive elements in the meaning of moral statements has been much misunderstood. The prescriptive meaning is the function all normative and evaluative statements have of guiding our actions. This shows up in the fact that someone who makes one about his own proposed actions but does not act accordingly exposes himself to a charge of speaking insincerely, as also does someone who makes one about other people’s actions but does not will them (in the above broad sense) so to act.

The descriptive meaning is the standard or criterion or reason or principle in accordance with which the statement is made. For example, if I say, ‘You ought not to say that, because it would be a lie,’ I am applying the principle that one ought not to tell lies. The ‘because’-clause does not merely repeat the ‘ought’-statement; it adds a reason for it. A common mistake is to confuse the content of moral statements with the reasons for them. That this is a mistake is shown by the fact that different people might make the same moral statement for quite different reasons; they might disagree radically in their moral principles. They would then be giving the same prescription, but disagreeing in their reasons for it.

Likewise, two people who differ about a moral question, one saying, ‘He ought,’ and the other, ‘He ought not,’ are affirming and rejecting, respectively, the same moral statement; otherwise they would not be disagreeing.That is what is wrong with the kind of subjectivism mentioned above. The statement is the same because it contains the same universal prescription, which one of them accepts and the other rejects. The fact that they are disputing about the same statement, bound by the same logic, is what enables argument between them to begin, in order to seek a resolution of their dispute (see §3).

3 Prescriptivism defended

There are many confusions that have to be cleared up before we can understand the prescriptivist position. The first we have noticed already: prescriptivists hold that moral statements are expressions of volition (in a broad sense in which it covers Kant’s rational will and Aristotle’s *boulēsis* or rational desire). They do not hold that they are statements that the speaker in fact wills something. They are therefore not exposed to the charge that they make our duties depend on what we will, as if we could make something our duty by willing it. If that kind of subjectivism were correct, then if someone said that something was their duty they would mean that as a matter of fact they willed it; and if they really did will it, it would be impossible to refute them. Rather, prescriptivists hold that in making a moral statement we are expressing our rational will; and if someone else wills something different, the disagreement has to be resolved by reason, that is, by determining which prescription can be rationally willed in the light of all the nonmoral facts, and respecting the logical property of universalizability (see §2), which, as Kant again saw, affords a powerful weapon in moral argument.

Opponents of prescriptivism and in general of ethical internalism commonly object that it is possible for persons to make a moral statement but to have no disposition to act on it nor to desire others to act on it (see Moral motivation §§1-3). They might be weak-willed persons or akratic, or satanists, who do wrong acts just because

they are wrong, or amoralists who do not accept moral statements as guides to action (see Akrasia). Answers to these objections have been put forward by Hare (1992a, 1992b: 98, and 1981 respectively). They require careful distinctions between different senses in which one can think that something ought to be done, not all of which are prescriptive.

The prescriptive sense of words like ‘ought’ is their central but not their only sense, and the existence of other senses easily gives colour to objections of this sort. The fact that moral statements carry descriptive as well as prescriptive meaning also makes it easy for descriptivists, attending only to this descriptive meaning, to argue that the statements are purely descriptive, that is, that their meaning is determined by their truth conditions and by nothing else. Often such arguments are reinforced by appeals to the surface grammar of moral statements, which are commonly in the declarative or indicative mood (though ‘ought’-statements are an exception). But the fact that such statements do have descriptive meaning, determined by truth conditions, alongside their prescriptive meaning is quite enough to explain such phenomena. These, however, do not show that they lack prescriptive meaning, nor that this is not central.

Moral words fall into two classes, according to how tightly the two parts of their meaning are tied to them. The distinction is sometimes made in terms of a contrast between ‘thin’ and ‘thick’ moral concepts. There are first the primarily prescriptive (or primarily evaluative) words like ‘ought’, ‘wrong’ and ‘good’, whose prescriptive meaning is more firmly attached to them than their descriptive. If someone starts making some of their moral judgments by entirely new standards (they have become a pacifist, say, or a vegetarian), they can still go on using those words, in the same senses, to express and apply the new standards.

By contrast there are other words, the secondarily prescriptive, whose prescriptive meaning is tied to them more loosely than their descriptive. If the standards encapsulated in these words are discarded, as in principle they can be, the words have to be discarded with them (see Hare 1963: 189, footnote).

A common move of descriptivists is to claim that there is no real difference in prescriptivity between prescriptive and descriptive speech acts, because either can be used to guide action. To say that a man has frequently beaten his first wife before their divorce may provide an incentive not to become his second; yet, it is claimed, the statement that he indulged in wife-beating is all the same descriptive. But a lady such as ‘O’ who liked to be beaten might not call him a bad husband (Réage 1954: 17). Thus ‘wife-beater’ is only contingently a pejorative term, but ‘bad husband’ is necessarily so. That is the difference between inherently and merely contingently action-guiding expressions. Only the former are genuinely prescriptive.

In spite of appearances, prescriptivism has the advantage over descriptivist theories when it comes to establishing the rationality and objectivity of moral thinking. Objectivity may be defined as acceptability to all rational thinkers. All forms of descriptivism have to rely on appeals either to generally accepted moral convictions, which may vary from one culture to another or to the meanings of words (especially secondarily prescriptive words) which encapsulate such culturally relative values. Only prescriptivists can rely solely on the logic of moral statements, which can be invariant between cultures; they can ask, as Kant did, what one can will to be a universal law, applicable whoever occupies whatever role in a situation. Faced with this question, rational thinkers will agree on the answer (see Moral knowledge §3). They will thus come to agree on principles giving the truth-conditions of moral statements - principles which are acceptable to all rational thinkers and depend solely on logic and the nonmoral facts. This is the only way to secure objective, culture-invariant, truth for moral statements (Hare 1993).

Presocratic philosophy

The Presocratics were the first Western philosophers. The most celebrated are Thales, Anaximander, Pythagoras, Heraclitus, Parmenides, Zeno of Elea, Empedocles, Anaxagoras and Democritus. Active in Greece throughout the sixth and fifth centuries BC*, they concentrated on cosmogony and cosmology - the tasks of explaining the world's origin and order, without recourse to mythology.*

Socrates (469-399 BC) is perceived as marking a watershed in philosophy - a shift of focus from the origin and nature of the universe to human values. 'Presocratic' philosophy thus represents the era intellectually antecedent to Socrates, even though its exponents included contemporaries of his (some his juniors). Those thinkers contemporary with Socrates who shared his concentration on human values it is better not to call Presocratic (see Sophists). No complete Presocratic text survives. We have only later writers' quotations ('fragments'), summaries (see Doxography), criticisms, and so on, from which to glimpse the originals.

A mythological construction of the world was already integral to the earliest poetry familiar to the Greeks (*c*.700 BC) (see Hesiod; Homer). Philosophers' rationalizations of this picture concentrated initially on such questions as what the world's primeval stuff is, why the earth remains stable and, more generally, what made the world orderly. In time *kosmos* ('ordering'), came to mean 'world'. To explain cosmic order, biological, mechanical and even political models were developed. However, Presocratic philosophy was interested equally in the human soul and its destiny (see Psychē), and never altogether ignored human values. Another dominant issue was the possibility of human knowledge.

The main movements and phases were as follows. The three sixth-century BC Milesian philosophers, starting with Thales, were monists: each posited a single primeval stuff - for example, water, air. These came to function not just as the world's originative stuff but also perhaps as its enduring substrate (see Archē; Thales §2; Anaximander §§2-3; Anaximenes; Monism).

Pythagoreanism, although a secretive movement with cultic leanings, was highly influential throughout this era. Beyond a concern with the soul and survival, it promoted a mathematicizing approach to cosmology (see Pythagoras §1; Pythagoreanism §2; Orphism; Philolaus §§2-3).

Heraclitus (*c*.540-480 BC) kept the formal focus on the cosmos and the soul, but his approach was largely governed by metaphysical concerns, especially the paradoxical interdependence of opposites (see Heraclitus §3). Metaphysics and logic took centre stage soon after in the Eleatic movement, initiated by Parmenides and continued by Zeno of Elea and Melissus. Eleaticism was a radical critique of ordinary notions of being, defending instead a strict monism which outlawed all phenomenal distinctions and changes as illusory (see also Gorgias §3).

The later fifth-century BC cosmologists sought to deflect this Eleatic critique. Most were pluralists, positing more than one underlying element. Their contributions culminated in the atomic system of Democritus, which reduced all reality to atoms and void, conceding much to Eleaticism (see Atomism, ancient; Anaxagoras; Empedocles; Leucippus)

Presocratic philosophy is often seen as materialistic. However, no philosopher before Leucippus and Democritus reduced life and intelligence to something inanimate. Previous Presocratics considered these ineliminably present in things - either as already intrinsic to the primordial stuff(s) or, in Anaxagoras' system, by virtue of an irreducible dualism of mind and matter.

Presupposition

There are various senses in which one statement may be said to 'presuppose' another, senses which are in permanent danger of being confused. Prominent among them are Strawsonian presupposition, a relation which obtains between statements when the falsity of one deprives the other of truth-value (for example, 'There was such a person as Kepler' is a Strawsonian presupposition of 'Kepler died in misery'); semantic presupposition, which obtains between a statement and a particular use of a sentence type, when the falsity of the statement means that that use will not after all constitute the making of a statement (for example, 'The name "Kepler" has a bearer' is a semantic presupposition of 'Kepler died in misery'); and pragmatic presupposition, a broader notion exemplified by the legitimate presumption that accepting or denying the statement 'Fred knows that the earth moves' means accepting 'The earth moves'.

1 Introduction

In most conversations a certain amount of knowledge is assumed by the parties. Conversing with people whom we know well, we can take it for granted that they know who we are and what we have recently been doing, along with much else. Ordinarily, 'presuppositions' are nothing other than these assumed parts of the conversational background.

The notions of presupposition which have been of greatest concern to linguists and philosophers, however, have been more narrowly defined (but see §4 below), typically being concerned with the way certain phrases or constructions indicate that the speaker is making a presupposition in the ordinary sense. So, if I affirm 'Wellington's victory at Waterloo was his greatest triumph', my form of words indicates that I am presupposing that Wellington was the victor at Waterloo and asserting that it was his greatest triumph. However, the commonly stressed opposition between presupposition and assertion is in some measure misleading. In asking 'Is Tony going to Salzburg again this summer?', I presuppose that he has been there before and inquire whether he intends to go there in the future; no assertion has been made.

This phenomenon may be closely related to another. If I affirm

(1) All John's children are asleep,

I presuppose that John has children and assert that they are asleep. In affirming

(2) If all John's children are asleep, we should not leave the house,

I do not make the same assertion, but I do still presuppose that John has children. It is this that linguists have in mind when they speak of presuppositions being easily 'inherited': they are often (but not always) retained even when the clauses that convey them are sententially embedded so as to lose their own assertive force. Much of the work done by linguists on this topic has been concerned with identifying constructions in which presuppositions do not survive, and to explain why inheritance is blocked (see various authors collected in Davies 1991).

Philosophers writing on the subject, by contrast, have largely been concerned to elucidate the nature of presupposition: to explain what one thing's presupposing another really amounts to; and to specify the kinds of item between which the relation of presupposition obtains.

2 Strawsonian presupposition

The writer most responsible for bringing the notion of presupposition to the attention of philosophers is P.F. Strawson, from whose work (1) above is drawn. Commenting on the situation of somebody who makes an assertion by uttering (1), Strawson remarks that

> he will not normally, or properly, say this, unless he believes that John has children…. But suppose…John has no children. Then is it true or false that all John's children are asleep? Either answer would seem to be misleading. But we are not compelled to give either answer. We can, and normally should, say that, since John has no children, the question does not arise.
>
> (1952: 173-4)

Strawson is eventually led to advance the following general explanation: ‘if [statement] *S′* is a necessary condition of the *truth or falsity* of [statement] *S*,…then *S presupposes S*Čprime;’ (1952: 175; original emphasis). So the statement that John has children is a ‘Strawsonian presupposition’ of the statement that all John’s children are asleep; for unless the former is true the latter is neither true nor false. Strawson’s talk of a ‘question [which] does not arise’ is liable to mislead. If John has no children, then the question ‘Is statement (1) true or false?’ may be raised; but the correct answer will be that it is neither.

To understand the notion of Strawsonian presupposition properly, it is necessary to understand what exactly a statement is. Strawson distinguishes between declarative ‘sentences’ - linguistic types the use of which on various occasions of utterance enables people to say things - and the ‘statements’ thereby made. It is statements, not sentences, that are true or false. Should a presupposition fail, there will be a ‘truth-value gap’: a statement will qualify neither as true nor false. An analogous notion applies to other kinds of speech act. So a yes/no question *Q* may be said to presuppose a statement *S* if the truth of *S* is a necessary condition of *Q*’s being answered by ‘yes’ or ‘no’ (see Strawson 1954).

The notion of Strawsonian presupposition has certainly found important philosophical application. In Strawson’s own writings it forms the basis of a counter to Russell’s suggestion that simple sentences involving ‘definite descriptions’ - that is, sentences of the form ‘The *F* is *G*’ - are not of subject-predicate form (see Descriptions). Russell held that such a sentence is best analysed as an existential sentence, ‘There is one and only one *F*, and it is *G*’, whereby the statement that the *F* is *G* straightforwardly entails the existence of an *F*. Having attacked Russell’s arguments in its favour, it was on precisely this score that Strawson tried to refute the theory itself: he insisted that the statement that the present king of France is bald presupposes (rather than entails) that there is a present king of France (see Descriptions §4).

In assessing this suggestion, note that when contemplating statements which are neither true nor false, Strawson requires ‘false’ to bear a sense other than ‘not true’. This means that, in the first place, the difference between Strawson and Russell is less than might at first have been supposed. Since Strawson accepts Russell’s account of the conditions under which a statement made by uttering ‘The *F* is *G*’ will be true, he agrees *ipso facto* with his account of the conditions under which such a statement is not true. They differ only over the conditions for such a statement to be false, Strawson deeming such statements to be neither true nor false in circumstances where Russell would deem them straightforwardly false.

In the second place, however, we are driven to wonder what Strawson means by calling a statement ‘false’, given that it is not a synonym for ‘not true’. It is reasonable to expect the attribution of falsity to a statement to be regulated by the principle that *S* is false just in case the negation of *S* is true, and this is a principle that Strawson’s treatment respects; indeed, it seems that he takes this principle to be explanatory of the notion of falsity. But then it becomes crucial to have a test for identifying the negation of a statement, especially for natural languages, where the syntax does not necessarily make this obvious. Since Strawson’s reluctance to classify ‘The king of France is bald’ as false when there is no king of France stems from a desire to reserve that attribution for the case in which there is a king of France and he is not bald, it is plain that Strawson regards the latter case as the proper negation of this statement. This, indeed, is what one might expect, given that Strawson is defending the view that ‘The *F* is *G*’ is a subject-predicate sentence. But the Russellian will want to draw a semantic distinction between ‘It is not the case that the king of France is bald’ and ‘The king of France is not bald’. This suggests that the issue between them ultimately turns, not upon questions concerning presupposition, but upon the proper treatment of negation (and other logical modifiers) in natural languages.

3 Semantic presupposition

A rather different notion of presupposition is suggested by Frege: ‘If anything is asserted, there is always an obvious presupposition that the simple or compound proper names used have a reference [*Bedeutung*]. If therefore one asserts "Kepler died in misery", there is a presupposition that the name "Kepler" designates something’ (1892: 40). In order to see the difference between this notion of presupposition and Strawson’s, it helps to make one assumption about statements; namely, that the same statement can be made in a variety of languages. Suppose, then, that there is a sequence of Chinese characters by the inscription of which it may be stated that Kepler died in misery. Such an inscription will certainly not contain the name ‘Kepler’, so it will not impede the making of that

statement, should the English (or German) name 'Kepler' lack a reference. But in that case,

(3) The name 'Kepler' has a reference

plainly is not a Strawsonian presupposition of

(4) Kepler died in misery,

that is, of the statement made by uttering (4). For the latter statement could be made by inscribing the Chinese characters instead, and the statement thereby made could have a truth-value even if (3) were false. What does qualify as a Strawsonian presupposition of (4) is the following statement:

(5) There was such a person as Kepler.

We need, then, to distinguish the new notion of presupposition, exemplified by (4) and (3), from that exemplified by (4) and (5).

In explicating this new notion, it helps to invoke again Strawson's distinction between a (declarative) sentence type - which is the bearer of meaning - and the statement made when the sentence is uttered or used - which is the bearer of truth-value. For with that distinction in mind, we see that the new notion is not a relation between statements, but a relation between a sentence - as used (with a particular meaning) upon a particular occasion - and a statement. Thus, the sentence 'You are drunk' (as used on a particular occasion) presupposes that the speaker is addressing somebody, in the sense that if not, then the use of that sentence on a particular occasion will not constitute the making of a statement. Generally, then:

A use of sentence σ in circumstance *c* presupposes statement *S* in so far as the truth of *S* is necessary for that use to qualify as the making of a statement.

When *S* and σ are so related, we may say that *S* is a 'semantic presupposition' of sentence σ, relative to *c*.

4 Pragmatic presupposition

Whatever the differences between them, Strawsonian and semantic presupposition are alike in depending upon the content of statements, or the meanings of sentence types. That is to say, they are alike in abstracting from the particular conversational purposes of the person uttering the sentence. In this respect they differ from another presupposition relation in which the actual speaker looms much larger. Following Stalnaker (1974), we might say that

A statement *S*′ is a 'pragmatic presupposition' of a statement *S* in so far as a hearer may reasonably infer that the speaker accepts *S*′ either from their acceptance of *S* or from their denial of it.

One salient difference between this explication and the definition of a Strawsonian presupposition is that the notions of truth and falsity have been replaced by those of acceptance and denial (acceptance of the negation). Another is the introduction of the notion of a hearer's reasonable inference - reasonable, that is, by the lights of a well-run conversation.

Whether one statement is a pragmatic presupposition of another depends crucially, then, upon what constitutes a well-run conversation, a notion philosophers have tried to explicate by formulating general 'conversational maxims', such as the rule (R) that one's hearer may assume that one is making the logically strongest relevant statement compatible with one's beliefs. To illustrate this, and to show how a pragmatic presupposition might obtain even when a Strawsonian presupposition does not, suppose that speakers are known to abide by (R), and consider the statements *S*: 'Fred knows that the earth moves' and *S*′: 'The earth moves'. *S*′ is not a Strawsonian presupposition of *S*: when *S*′ is false, we may conclude simply that Fred's belief is not in fact knowledge and that *S* itself is straightforwardly false. All the same, a strong case can be made for the contention that *S*′ is a pragmatic presupposition of *S*: I may reasonably infer that a speaker accepts *S*′, should I hear them either accepting or denying *S* (see Stalnaker 1974). The case of accepting *S* presents no difficulty; and a denial of *S* amounts to an assertion of 'Fred doesn't know that the earth moves', an assertion which I may suppose that the speaker would not have made had they accepted the stronger statement 'The earth does not move'.

Price, Richard (1723-91)

Richard Price was a Welsh dissenting minister who contributed widely to philosophy and public life in latter-eighteenth-century Britain. The leading British ethical rationalist of the period, Price did much to establish intuitionistic and deontological traditions in ethics. He put forward searching criticisms of alternative empiricist conceptions, arguing that they could not account for morality's necessity and that they lacked an adequate theory of moral agency. More constructively, he argued that, contrary to the empiricists, all knowledge depends on the contribution of reason, and that rationalistic moral knowledge is no more problematic in principle than ordinary empirical knowledge. He also articulated a normative ethics of integrity that stressed the duty diligently to search out moral truth and then to act on the truth as one sees it.

As a political philosopher, Price made fundamental contributions through his doctrine of liberty as self-determination. The moral duty individuals have to determine themselves by their best moral judgment, Price believed, ultimately grounds the values of political liberty, independence, and democracy as well. Price's radicalism on these scores earned him the famous opposition of Edmund Burke. Nor was Price's sponsorship of these ideas simply theoretical. He was an important friend of the American Revolution, and his pamphlets analysing and defending it were taken seriously by proponents and opponents alike.

Price also did important work on the mathematical theory of probability and in proposing and instituting various social and economic reforms and practices upon its basis. He was instrumental in making Thomas Bayes' ideas about probability accessible to the learned world, and in making use of these and other probabilistic theories in developing insurance, self-help, and other financial schemes.

1 Life and works

Richard Price was born on 23 February 1723 at Tynton, Llangeinor, Glamorgan into a family that, on his father's side, had been involved in Welsh dissent for two generations. Much of Price's normative outlook can be understood against this background - his emphasis on piety, integrity, self-determination and freedom of conscience. Price's meta-ethics, on the other hand, was a reaction against Calvinist theological voluntarism of the sort represented by his dissenting minister father, Rice Price. As son Richard saw it, moral propositions claim by their very nature to represent an objective, necessary and non-arbitrary order. Voluntarism, whether secular or divine, must ultimately lead to moral scepticism (see Moral scepticism; Voluntarism). Consequently, Price believed that the moral core of religious dissent, to which he would be loyal throughout his life, could only be preserved by giving it a rationalist foundation. Together with articulating dissent's normative dimensions, this was Price's central philosophical project.

Price's great ethical work was *A Review of the Principal Questions and Difficulties in Morals* (1758). It is the repository of all his major ideas on ethics and the source of many of his political theories. The year *A Review* appeared, Price accepted a post at a Presbyterian church in Newington Green, near London. During the next fifteen years there, he published on an astonishing variety of topics. In 1764 and 1765 he edited Thomas Bayes' seminal writings on probability theory, publishing them in the *Transactions* of the Royal Society. *Four Dissertations*, a theological work, appeared in 1767. In 1770 and 1771 Price contributed three further papers to *Transactions*, one on astronomy and two on calculating life-expectancy and annuities, respectively. These last were incorporated into *Observations on Reversionary Payments* (1771), which established Price's considerable reputation in the field of insurance. It went through three editions, and part was expanded and published separately as *An Appeal to the Public on the Subject of the National Debt* in 1772.

Price's greatest fame, however, came from his political writings, beginning with *Observations on the Nature of Civil Liberty* (1776), a pamphlet that sketched his political philosophy and defended the American Revolution on its basis. Seven editions appeared during its first year of publication alone. Its major philosophical thesis was that states acquire legitimacy as trustees for consenting, self-determining moral agents, and have thereby a right to self-determination as representatives of their citizens. If, consequently, the American colonists wanted to govern themselves, that was both their right and duty. Price wrote several further works analysing and praising the American Revolution and one, *A Discourse on the Love of Our Country* (1789), celebrating the French Revolution, which drew Edmund Burke's ire in his *Reflections on the Revolution in France* (1790) (see Burke, E.).

Throughout this period of extraordinary creativity and prominence, Price remained active in communities of dissent. He resigned his post at Newington Green in 1783, but continued an active participant there, as he did in St Thomas' Square, Hackney, to which he removed in 1787. His final sermon at Hackney came just months before his death.

2 Meta-ethics

Price advanced a rationalist meta-ethics along with a critique of the moral sense theories of Francis Hutcheson and David Hume, turning against them arguments Hutcheson had used to criticize secular and theological voluntarism (see Hume, D.; Hutcheson, F.; Moral sense theories). Hutcheson (1725) had argued that moral good and evil are simple, irreducible ideas. Any reductionism, including voluntarism must fail, therefore, since it is one thing to say that I will suffer sanctions if I fail to act as commanded, but another to say that violation is morally wrong or evil and that sanctions will be deserved. Alternatively, if voluntarists hold that moral good consists in obeying authoritative commands, they then assume a background moral fact that can have no voluntarist explanation, namely, that these commands are ones that persons should obey.

Because he held an empiricist theory of ideas, Hutcheson concluded from this irreducibility that there is a distinctive moral sense which receives moral ideas. Price agreed that moral ideas are irreducible, but argued that attributing them to a contingent sense or sensibility makes them ultimately no less posited than if they were to depend on arbitrary command. According to Hutcheson, benevolence is morally good, not because it intrinsically or necessarily warrants approbation, but because beings with our moral sense (including God) happen to approve it.

There are several different elements to the Pricean critique of empiricism. First, Price argued that moral judgments make an implicit claim to *objectivity*, while any empiricist account must understand them ultimately to concern subjective experience. Second, moral judgments attribute properties based on the *intrinsic nature* of their objects. Third, they attribute these properties *eternally* and *necessarily*. Fourth and finally, moral judgments attribute properties independently of any *arbitrary* standard. When we attribute viciousness to dishonesty, for example, we implicitly hold that, by its very nature, dishonesty has a property that depends not on any response we happen to have, standard we arbitrarily apply, or any other contingent feature.

What misled the empiricists, Price believed, was their general theory of ideas. Price insisted that reason is itself a source of ideas. Were it not, we would lack a whole host of concepts that cannot possibly come from experience alone. Following Ralph Cudworth (whose *Treatise on Eternal and Immutable Morality* appeared posthumously in 1731, after Hutcheson's *Inquiry*), Price maintained that the notions of substance, duration, space, causation and necessity, among others, cannot come from sense experience, and so must be due to reason or the understanding (see Cudworth, R.). Nor should we doubt that reason is also the source of moral ideas. A rational basis for moral ideas, on the one hand, and any basis at all for the notions central to the science of nature, on the other, stand or fall together.

Price concluded that moral claims can be known by direct rational intuition. Some, the 'heads' of virtue, are self-evident. These are 'general principles', such as those enjoining veracity, fidelity, gratitude, justice and so on, that concern what it is right and wrong to do. Principles at this level of generality are bound to conflict in actual cases, however, and Price held that it is not self-evident what a person should do when they do. What is self-evident to reason is what moral considerations are relevant - what persons should and should not do, other things being equal.

Price's meta-ethics thus amounted to a metaphysical realism combined with a rational intuitionist epistemology (see Realism and antirealism). Moral propositions are like mathematical claims, Price thought. Their truth is determined by correspondence to facts about an objective, eternal, necessary order. And they are known through a rational perception of the same kind.

But how then is moral perception or knowledge related to motivation? One way this question arises is in connection with obligation, which Price's contemporaries tended to see as intrinsically tied to motive. Indeed some writers, rationalists *and* empiricists, maintained that obligation just *is* a motive, perhaps inescapable, perhaps distinctively moral. Price resisted this identification, holding that 'obligatory' is another name for the fundamental

irreducible moral notion. Obligation consists in the eternal and immutable moral features of the objective situation in which persons find themselves, not on their motivational state. At the same time, Price held that the *perception* of irreducible moral features *is* linked to motivation and, indeed, that 'it is not conceivable' that a person who perceives that an action ought to be done 'can remain uninfluenced, or want a motive' (1758: 186). But if motivation is no part of the perceived ethical facts, and if the faculty of perception is the understanding (the same faculty involved in the motivationally inert perception of mathematical facts), what explains this necessary motivation? What makes it, as Hume put it, 'universally forcible and obligatory'?

Price's reply was a doctrine of rationally necessary affect and motive, of which this was but one example. The only alternative to believing that moral properties are objective, eternal and immutable is to hold that nothing has a nature that determines its moral properties. This would be true no less of God than of other beings. But we can hardly deny, Price argues, that God is good simply by virtue of his nature. And this commits us to the conclusion that goodness is an eternal, objective and immutable property of a being with such a nature. Moreover, there are other aspects of God's nature that would seem equally essential and not merely contingently true of him. For example, it hardly seems that it could be merely contingently true that God is pleased by virtue or by the perception of beauty generally, or that he is benevolent, or that he desires what is morally good and just for his creatures. But if we accept that affects and motives of these sorts are essential to God, Price argues, we should also believe that they are essential to rational nature, rather than deriving from some contingent or 'implanted' motive or sense. It follows that being moved by the perception of ethical facts is intrinsic to the understanding.

3 Normative ethics

Just as Price rejected empiricist metaethics, so also did he deny the proto-utilitarian, normative ethics it was frequently used to support. The 'heads of virtue' are various and distinct, and although benevolence is one of these, the others are not reducible to it. Piety, veracity, justice and the other 'heads' are self-evidently intrinsically morally relevant, regardless of their actual or usual consequences.

Price distinguished between the virtue of actions and the virtue of agents. The former concerns whether, all things considered, an action is objectively right, irrespective of the motives that actually led or will lead to it. An action manifests the agent's virtue, on the other hand, only if it is done from the proper motives. Most importantly, Price held, actions manifest agent-virtue only when the agent 'acts from a consciousness of rectitude and with a regard to it as his rule and end' (1758: 184). Behind this thesis lies Price's doctrine that genuine agency entails self-government, and that this involves a person guiding themselves by their convictions concerning what they should do. If moral virtue is a virtue of agents, therefore, it must include this element.

For Price, the virtuous agent is a person of integrity, concerned to determine what they should do and, having determined that, to act as they think they should. The first duty of moral agents is diligently to determine the virtuous act, to see under what self-evident general principles the alternatives before them fall, and carefully to judge what they should do, all things considered. God has made human beings so that moral truth is tolerably accessible to them if they will but use their understanding attentively. Having made a conscientious judgment, Price held, a moral agent should then follow their conscience 'steadily and faithfully', even if it should turn out to have been mistaken.

Price distinguishes between the abstract and practical virtue of actions. The abstract virtue of an act is its moral quality, considered independently of the agent's motives and beliefs, including those concerning what the agent should do. This is what moral agents attempt to determine in deliberation: 'What is the right thing to do owing to the objective features of my practical context?' Practical virtue, by contrast, depends on agents' beliefs about the alternatives confronting them, including, importantly, their beliefs concerning the abstract virtue of these alternatives. This analytical distinction grounds an important Pricean normative doctrine, namely, that when moral agents have seriously deliberated, what they then should do is what they think they should do. Practical virtue is thus not just a moral quality an action would have if the objective features of alternatives confronting them were as the agent believed. If the agent makes a serious judgment that they should do something, then they really should do it. To act otherwise would be to compromise their integrity.

Consequently, while Price's rational intuitionism stresses eternal and immutable moral qualities actions have owing to their objective, intrinsic nature, these concern only abstract virtue, which is, however, of the first

importance in deliberation, as agents diligently seek to determine the abstract moral qualities of actions before them. But once deliberation is terminated and agents have formed considered beliefs, what they should then do is a matter of practical rather than abstract virtue. They should follow their conscientious judgment.

Coinciding in this normative doctrine are proto-Kantian theories of self-determining agency and character (see Kant, I.; Kantian ethics). Capacity to act on an independent judgment of what one ought to do is what makes a being a self-determining agent in the first place, and moral virtue consists in the excellent exercise of this capacity. Sometimes, indeed, Price seems to count any moral failure as a failure of agency, creating puzzles about how vice can ever be imputed to an agent.

4 Political philosophy

The idea that moral persons are autonomous and independent forms the basis of Price's political philosophy no less than of his ethics. He begins his *Observations on the Nature of Civil Liberty* with a discussion of four different kinds of liberty - physical liberty, moral liberty, religious liberty and civil liberty - arguing that the central idea running through them all is self-government. Physical and moral liberty are powers of self-determining agency, the latter, the power of following conscience. The third and fourth ideas, by contrast, are political rather than moral forms of liberty. A political order establishes religious liberty when each can exercise the form of religion they think best. And it establishes civil liberty when it is itself self-determining, governing itself 'without being subject to the impositions of any power' (1776: 3).

The central idea of Price's political philosophy is that the proper contrary of liberty is not hindrance, but slavery. A person is free when they can determine for themselves what they will do, and they are unfree when they are subject to arbitrary authority and control. The obstacles to moral liberty can be internal or external, political obstacles to 'liberty of the citizen' being primarily external. Citizens are unfree when they are subject to the will of others, most prominently, to the will of those who claim political authority over them. It is not enough for citizens to be free, moreover, that they face no actual obstacles to self-direction. Being subject to a master who can control at their pleasure is sufficient, even if the master chooses not to exercise control.

Price's central political tenet was thus a doctrine of the equal dignity of all persons as independent and autonomous. Legitimate political authority can derive only from the will of the people, therefore, and never once and for all but only continuously, subject to their continuing advice and consent. When numbers make direct democracy impossible, public officials function as representatives, their authority always deriving from and being answerable to, the will of the people. It follows also, Price argued, that a justified polity must ensure the equal liberty of all citizens. Citizens must be secured from threats to their liberty, whether posed by alien forces, by other citizens, or by government itself. Mastery by others deprives citizens, not just of valuable goods, but of their dignity as persons.

Price's enthusiasm for the American Revolution derived from his seeing it as the expression of these ideas. America provided the hope of a government rooted in equal dignity and so, Price thought, 'a new prospect in human affairs', 'beginning a new aera in the history of mankind' (1776-89: 17). To his American friends he recommended representative democracy, with legislators being frequently held to free elections, as well as a variety of measures designed to restrict entrenched power, including religious liberty and the abolition of primogeniture and all hereditary honours and titles. One thing that tempered his enthusiasm was the African slave trade (see Slavery) for which Price had nothing but scorn.

Prichard, Harold Arthur (1871-1947)

One of the most influential Oxford philosophers of the twentieth century, Prichard was White's Professor of Moral Philosophy there from 1928 to 1937. His work combines epistemological realism and moral intuitionism. From 1906 onwards Prichard was active with the Oxford realists, who held, against idealists, that reality exists independently of mind, that knowledge is of reality, and that common-sense realism is correct. In ethics, he was the leader of the Oxford intuitionists who held, against utilitarianism, that common-sense morality is correct, its duties are known non-inferentially, and are an irreducible plurality of distinct kinds of act. His philosophical style displays concentration on specific problems, carefully using ordinary language to make precise distinctions in the absence of general theory. He influenced Oxford's next generation of Austin, Ryle, Hart and Berlin, who attended his classes and, occasionally, his 'philosophers' teas'.

1 Epistemological realism

Early in this century philosophy in Oxford was dominated by the opposition between idealists, such as T.H. Green, F.H. Bradley and Bernard Bosanquet, who held that mind constitutes reality, and the realists, such as J. Cook Wilson, H.W.B. Joseph, W.D. Ross and Prichard himself, who held that reality exists independently of mind (see Idealism). Prichard wrote his only book,*Kant's Theory of Knowledge* (1909), as a realist critique of Kant's transcendental analytic, and thereby developed the metaphysical and epistemological positions of the realist school. They are: (1) reality exists independently of mind; (2) if reality depends on mind then 'knowing is making', and mind makes reality. But (3) knowing is not making; knowing is being certain. Since we know when we know and know when we believe, as we show in choosing which word to use, it follows that knowledge is known in itself, while believing is known in relation to knowing (Urmson 1988).

Regarding perception, Prichard argues for a dualism of minds and objects and for common-sense realism. Prichard accuses Kant, and in other writings, Descartes, Locke, Berkeley, Hume and Russell, of wrongly hypostatizing 'appearances' when talking of how things themselves appear, thereby creating an intermediate entity variously called 'idea', 'representation', 'sensation', 'impression' or 'sense-datum'. These philosophers then quarrel over whether appearances copy reality or compose it. But they have given themselves an illusory problem.

2 Moral intuitionism

Prichard used the term 'intuitionist' to contrast his moral philosophy with that of the utilitarians. We can best approach his position by considering his greatest essay 'Does Moral Philosophy rest on a Mistake?' (1912). His affirmative response to this question is not modest, since the 'mistake' includes all moralists from Socrates to G.E. Moore. Their mistake is the assumption that there is something that all morally right actions have in common, from which their rightness can be inferred. According to Prichard, however, right actions possess no such quality. Thus moral knowledge is not inferential, but intuitive. One instance of this mistake is the belief that motives are the criterion of rightness. In discussing this view critically Prichard distinguishes two kinds of motive: 'moral', or acting from the conscientious desire to do what is right; and 'virtuous', or acting from an intrinsically good desire, such as compassion. Whichever kind one invokes, however, Prichard denies that it provides a criterion of right action, since right actions are sometimes done from bad motives. Utilitarianism and other consequentialist theories of duty provide another instance of the mistake. Prichard rejects traditional utilitarianism because it reduces all duties to the single duty of maximizing happiness, whereas in fact duties are essentially plural. He likewise rejects Moore's 'ideal' utilitarianism, which postulates a fundamental duty of maximizing intrinsically good outcomes of any kind, because it wrongly implies that there is a fixed hierarchy of types of intrinsically good outcomes (see Moore, G.E. §1). Thus Prichard rejects all consequentialist theories, and to the consequentialist claim that only consequences can resolve dilemmas rejoins that there is no single answer to dilemmas. Joseph, Prichard's fellow intuitionist, laments these conclusions, saying they 'leave moral duties in a heap' - as indeed they do. (see Consequentialism; Utilitarianism)

Despite his many criticisms of previous moral theories, Prichard never doubted that there is moral knowledge. How is it possible? Prichard's critics usually answer for him, 'We know by intuition', and suggest, by rolling their eyes and other such body language, that intuition is rapid, unhearing and irrational. But more may be learned by attempting a new approach which connects Prichard's realism and his 'intuitionism'. As a realist, Prichard

supported a common-sense realism which features common-sense knowledge of mind-independent objects. In morals, Prichard everywhere appeals to ‘ordinary, unreflective morality’. Thus, the parallel claim is that the acts that are really right are the moral duties of ordinary morality. This realism of common-sense morality is composed of the kinds of actions connected with promising, truth-telling, helping the helpless, returning what one has borrowed, paying debts, returning kindnesses and so on. The suggestion is that although the different kinds of ordinary obligations have different structures, a child can be taught to recognize them. When young, obedience may require the threat of punishment, but later, Smith, who has borrowed Brown’s electric drill, knows that he ought to return it because it is a loan and not a gift. From this basis, one can argue that intuition has a real object, namely the character of the kinds of moral action that are our ordinary obligations (see Intuitionism in ethics §2).

Once Prichard’s conception of intuitive moral knowledge is understood in this way, it becomes intelligible why he insists that before we know our duty we must consider an act’s circumstances (for instance, when telling the truth about a wayward, dying son to a grieving mother) and its consequences (for instance, when a surgeon discusses a gory operation over dinner). But has Prichard not eliminated consequences as a criterion of rightness? Apparently only as the single criterion, for he insists that no moral theory omits consequences. This insistence causes him to raise the question ‘What is the relationship between an action and its consequences?’ Logically, he cannot identify an action with its consequences or motives. He first suggests that an action is ‘setting oneself to effect a change’ and later he decides that ‘acting is willing’. Either way, Prichard clearly distinguishes ‘motive’ from ‘intended consequences’ and associates action with the latter. In turn, that permits him to argue that, depending on what will be taken for granted, we may include the intended consequences within the description of the act.

The remainder of Prichard’s moral philosophy is remarkable in its subtlety, but also for working upon problems implicit in ‘Does Moral Philosophy Rest on a Mistake?’ Thus, in ‘Duty and Interest’ ([1928] 1949) Prichard considers whether the sense of duty is a sufficient motive or if duty must be motivated by desire, and thereby enters the internalist versus externalist debate. In his lectures on T.H. Green, he states that philosophers have mistakenly sought one moral justification of political obligation, whereas different political states have different problems, requiring different justifications. Other implications are developed in ‘Duty And Ignorance Of Fact’ ([1932] 1949). In asking if duty depends upon ignorance of facts, Prichard divides the question with regards to common morality. Which is correct: subjective duty, which depends upon knowledge of facts, or objective duty, which identifies duty with what is independent of mind? I cannot have a duty to help my distant, ailing aunt if I do not know of her plight but, equally, I have a duty to help the helpless. This problem deadened his capacity to finish ‘a book on morals’. The essay ‘The Obligation To Keep A Promise’ ([*c*.1940] 1949) raises a problem akin to moral realism. First, however, Prichard is puzzled about the question ‘What is promising?’ ‘I promised’ is a statement that is either true or false. ‘I promise’ is not; it seems more like an action. But then promising, as doing, seems to create an obligation, an idea apparently foreign to Prichard’s thought. J.L. Austin admired Prichard, and their exchange of letters on promising as doing attests to Prichard’s influence on the formation of Austin’s ‘performative utterances’ (see Austin, J.L. §3; Performatives).

Priestley, Joseph (1733-1804)

A major figure of the British Enlightenment, Joseph Priestley is best known as a scientist and for his discovery of oxygen, though he was by profession a theologian, and also wrote on politics and education - more, indeed, than on science or metaphysics. His philosophical speculations were generally brought to support his theological arguments and were usually structured in a rhetorical rather than in a formal, systematic mode. He was a Unitarian in theology, an associationist, determinist and monist, with a curiously spiritualized materialism dependent, in part at least, on his scientific studies.

Joseph Priestley was born near Leeds, Yorkshire, England in 1733. He was self-educated in science and philosophy, reading on his own Locke's *Essay concerning Human Understanding* (1689) (see Locke, J.), Isaac Watts' *Logic: or the Right Use of Reason* (1725), and Willem Jacob Gravesande's Newtonian *Mathematical Elements of Natural Philosophy* (1720-1). At 19 he went to Daventry Academy to become a minister. Daventry's theological text was Philip Doddridge's *Course of Lectures on the Principle Subjects in Pneumatology, Ethics and Divinity* (printed 1763), from which Priestley learned of the Cambridge Platonists and of the Newtonian physico-theologians. He also read, at Daventry, David Hartley's *Observations on Man, His Frame, His Duty, and His Expectations* (1749), a work of greatest influence on him, converting him to associationism and to the doctrine of philosophical necessity (determinism) (see Hartley, D.).

Initially failing as a dissenting minister, Priestley became a successful teacher of languages and *belles-lettres* at Warrington Academy. There also he began his scientific career, writing his *History and Present State of Electricity* (1767), to which were added experiments and observations of his own. In 1767 Priestley became a Unitarian minister in Leeds. There he commenced his career as a religious polemicist, wrote an *Essay on the First Principles of Government* (1768), from which Jeremy Bentham derived his utilitarianism, and continued his scientific work. For the *History and Present State of Discoveries relating to Vision, Light and Colours* (1772), he adopted some ideas of Rudjer Josef Boscovic, which he would subsequently use for his justification of materialism. He also wrote his first paper there, published in the *Philosophical Transactions* (1772) of the Royal Society of London, on the chemistry of gases.

He left Leeds in 1773, to become librarian and companion to Lord Shelburne. During this period he did the major part of his pneumatic chemistry and the major part of his formal metaphysical writing. Leaving Shelburne in 1780, he settled as a minister in Birmingham. There he spent much time defending his scientific and metaphyical ideas and continuing his religio-political attacks on Church establishment - to the point, finally, of inciting a riot which drove him from Birmingham to London in 1791 and then, in 1794, into exile in the USA. There he continued the activities of his Birmingham years, until he died at Northumberland, Pennsylvania in 1804.

Priestley's explicit attention to philosophical writing began with *An Examination of Dr. Reid's Inquiry …On the Principles of Common Sense, &c.* (1775), attacking Scottish Common Sense Philosophy for its 'vain multiplication' of separate, arbitrary, instinctive principles to explain perceptions (see Common Sense School; Reid, T.). To disprove this naïve nativism, Priestley undertook an edition of selected parts of Hartley's *Observations on Man*, published as *Hartley's Theory of the Human Mind* (1775). Shorn of its specific references to religion and of the physiological doctrine of vibrations, this was, none the less, the avenue by which David Hartley's previously neglected *Observations on Man* was made known to the eighteenth and early nineteenth centuries.

Only in his first introductory essay to *Hartley's Theory of the Human Mind* does Priestley go beyond the *Observations on Man*, in which he was led into the most original of his metaphysical writing. In summarizing the physiological base suggested for associationism, Priestley asserted that Hartley's 'elementary' body mediating between mind and brain was unnecessary, and declared: 'I rather think that the whole of man is of some uniform composition, and that the property of perception…is the result of such an organical structure as that of the brain'.

This declaration provoked an outcry, prompting Priestley to write his *Disquisitions relating to Matter and Spirit* (1777). Into the *Disquisitions* Priestley poured the results of his thinking over the previous decades. 'Modern philosophical dualism' had no support from Scripture and led to the insolvable problem of interacting entities,

matter and spirit, defined so that there was nothing in common between them. It also took no heed of recent discoveries in electricity, optics and chemistry. Far from being solid, inert and impenetrable, matter could be defined as a ‘compages’ of geometrical points, surrounded by spheres of alternating repulsive and attractive force.

With this publication no defence was sufficient to escape from accusations of materialist atheism, and that charge was enhanced by the publication of Priestley’s *Doctrine of Philosophical Necessity Illustrated* (1777), in which he insisted that people’s actions were determined by laws of nature. Priestley’s arguments were ingenuous, emphasizing similarities between his doctrine and that of freewill: ‘All the liberty… that I say a man has not, is that of doing several things when all the previous circumstances… are precisely the same’. None the less, the doctrine of philosophical necessity was representative of the relation of cause and effect, from which Priestley derived his arguments for the being of God, and he insisted that will is determined by motive, and motive by state of mind and view of things. When these remain the same, people will always make the same choice and determination.

Attacked for his views, Priestley responded - in such books as *A Free Discussion of the Doctrines of Materialism and Philosophical Necessity* (1778) - that nothing could be known of matter but its properties; that his monism could be called ‘wholly spiritual’ as easily as ‘wholly material’; and that, by his description ‘matter is…resolved into nothing but the *divine agency*, exerted according to certain rules’.

These proposals were too radical, and his anti-establishment persona too obvious, for Priestley’s ideas to win any permanent acceptance in Britain. His achievements in all but science were soon forgotten, and Priestley has remained one of the neglected philosophical writers of his age.

ROBERT E. SCHOFIELD

List of works

Priestley, J. (1972) *The Theological and Miscellaneous Works of Joseph Priestley, LL.D. F.R.S. &c.*, ed. J.T. Rutt, New York: Kraus, 1972, 25 vols.(Contains all the philosophical works, but on the prefaces of the science books. Most of the latter, however, were reprinted separately by Kraus.)

Primary-secondary distinction

The terminology of 'primary and secondary qualities' is taken from the writings of John Locke. It has come to express a position on the nature of sensory qualities - those which we attribute to physical objects as a result of the sensuous character of sensations they produce when they are perceived correctly by us. Since our senses can be differentiated from each other by the type of sensations they produce, sensory qualities are what Aristotle called 'proper sensibles' - those perceptible by one sense only. Colours, sounds, scents and tastes are always regarded as proper to their respective senses. What are the proper sensibles of touch, and whether there is similarly a single family of them, is a matter of controversy; but temperature at least is standardly regarded as proper to this sense. It is such sensory qualities that are candidates for being given the status of secondary qualities.

To regard sensory qualities as secondary is to hold that an object's possession of one is simply a matter of its being disposed to occasion a certain type of sensation when perceived; the object in itself possesses no sensuous character. Primary qualities, by contrast, are those which characterize the fundamental nature of the physical world as it is in itself. They are always taken to include geometrical attributes, and often some space-occupying feature; Locke's candidate for this latter was solidity. Although the terminology dates from the seventeenth century, this general doctrine goes back to the Greek atomists.

1 Locke's account

Although the distinction between primary and secondary qualities is of ancient lineage, the terminology became current through the writings of John Locke, who was consciously drawing on the work of his older contemporary Robert Boyle. Although a not unrelated distinction between primary and secondary attributes of matter is to be found in Medieval philosophy, when Boyle writes of 'secondary qualities, if I may so call them', he indicates that he took himself to be coining an expression to bear the sense that interests us. The distinction as it is drawn by Boyle and Locke is not one that centrally concerns the nature of sensory qualities or the relation between sensory states and physical reality, but rather the issue of what are fundamental and what are derivative attributes of material objects. This is clearly seen when one considers Locke's treatment of what are sometimes termed 'tertiary qualities' - such as a fire's power to melt wax. Such qualities are in fact termed 'secondary' by Locke; they differ from what are usually regarded as secondary qualities - that is, sensory qualities - only in that the latter are immediately and the former are mediately perceived. By 'secondary' Locke in fact means *derived*, *resultant* or *supervenient*.

In order best to understand this, we should bear in mind the hypothesis that Locke adopts as the most plausible account of the material world: namely, corpuscularianism, or what we would call atomism (although Boyle defines a corpuscle as a coalition of *minima naturalia* - which are the genuine atoms - so that a corpuscle is closer to our modern idea of a molecule) (see Atomism, ancient). According to this view, everything material either is an atom - a small, naturally indivisible, solid body - or is a complex body consisting entirely of a number of such atoms. In any such complex body the constituent atoms will be arranged in a certain way, the technical term for such an arrangement being 'texture'. By 'quality' Locke means any feature of an object in virtue of which it has the power to affect another object. In virtue of the texture possessed by a complex object, as well as, perhaps, in virtue of the constituent atoms moving in relation to one another in the body (for example, vibrating), that object will possess certain powers - powers that no noncomplex, nontextured object could possess. All such powers are secondary qualities, since they derive from, or are secondary to, the arrangement and motion of the atoms constituting a complex body.

Thus there is no question for Locke as to whether a single atom may possess any secondary quality; such a thesis is analytically false. The only genuine question in this area concerns which of our ideas are excited by such derivative powers. It is an immediate consequence of this that no secondary quality is a universal or, as Boyle and Locke put it, 'catholic' attribute of matter, since they derive from particular, contingent configurations of atoms in complex bodies. By contrast, primary qualities are non-derivative, fundamental features of matter, and hence are possessed by everything material as such - even individual, simple atoms. ('Hence', because such writers regarded the idea that a quality could be underived and yet non-catholic - by having a bare, brute presence in some bodies but not in others - as a nonstarter. Primary qualities are fundamental in that they are essential attributes of matter as

such.) Roundness, for example, can count as a primary quality even though not everything material is round, since it is but a determination of figure, which is possessed universally by body. Secondary qualities are immediately perceived when they are powers to occasion perceptual sensation in us, mediately perceived when they are powers to effect changes in other material objects, which latter changes alone we perceive.

One might object that the figure of a cricket ball ought to be a secondary quality since it results from an arrangement of the ball’s constituent corpuscles. However, as far as the perception of the ball’s shape is concerned, the cricket ball could just as well be a single, very large atom; the shape of the mass of configured atoms that is the ball is identical to the shape that a single atom may possess. We can see cricket balls and we cannot see individual atoms; however, the power of a cricket ball to appear round is not crucially dependent on the inner complexity of the ball, but simply on its size; atoms are simply too small to see. Another way of putting this introduces a second defining feature of the primary-secondary quality distinction: primary qualities excite ideas in us which *resemble* those qualities, whereas secondary qualities do not. With secondary qualities mediately perceived, this is obvious; we have no (pre-theoretical) idea of what it is in the fire that gives it the power to melt wax. Locke says that such qualities are generally agreed to be ‘barely powers’. By this he of course does not mean that these powers are brute and ungrounded: they are grounded in the complex texture and perhaps motion of the object’s constituent atoms. What he means is that they are barely powers as far as our ideas of them are concerned. Locke’s view is that we are really not much better off when it comes to secondary qualities immediately perceived. Certain complex bodies have the power to excite various sensory states in us; it is in virtue of the texture and motion of an object’s constituent atoms that it appears, for example, coloured or warm or scented to us. There is no colour or warmth or scent in objects distinct from the arrangement and perhaps motion of such objects’ constituent atoms. So an object looks coloured because of such atomic facts; whereas, in contrast, a round object standardly looks round because it is round. This is all that Locke’s much-criticized notion of resemblance means.

2 The standard account

Primary and secondary qualities are usually not spoken of today as they were by Boyle and Locke, George Berkeley being the principal instrument of change. In Berkeley we find two switches in terminology. First, the term ‘secondary quality’ is restricted to sensory qualities. Hence the central philosophical issue in this area becomes that of the relation between our senses and the nature of matter. Second, upholders of the primary-secondary quality distinction are said to hold that secondary qualities exist only in us - colours, scents and so on are merely sensations in the mind. ‘Secondary’ thus came to mean, or at least connote, ‘in the mind’ rather than ‘derivative’. As an interpretation of Locke, this is half right and half wrong. For Locke, secondary qualities are certainly in bodies themselves. However, colours and so forth are merely in the mind. This is because colour, for example, is not a secondary quality for Locke; colour exists only in us, or in idea. When he wishes to advert to the corresponding secondary quality, he will use a phrase such as ‘colour as it exists in bodies’. Because of all this, the precise meaning of ‘secondary’ is somewhat indeterminate in modern writings, although the general issue at stake is clear: do the sensuous features that we experience when we perceive physical objects inherently and irreducibly characterize the physical objects themselves? Does the world as it is in itself possess sensuous character?

3 Reasons for the distinction

Two sets of reasons exist for drawing our distinction: the first consists of reasons that are broadly empirical in nature, the second a priori. Under the first would fall even Locke’s observation that secondary qualities can be altered by a merely mechanical process: for example, pounding certain substances changes their colour. How can this be unless such qualities are wholly subsumable under a merely mechanical account of the world? More recent discoveries concerning the precise nature of sensory perception allow a more detailed identification of such qualities with scientifically specifiable states of bodies. If, for example, an object’s taste just is that in a body which gives rise under normal conditions to gustatory experiences when that body is placed in the mouth, and we discover that what thus causes such experiences is some chemical feature of that body, then taste must be identified, without remainder, with such a feature. By contrast, the best account available of why, for example, certain objects look round is that they are round.

A priori considerations must also be relevant, however, since roughly the same set of qualities have been given secondary status for over two thousand years. Certain qualities of bodies can be singled out a priori as being

sensory in a distinctive sense. It is not just that such qualities are perceptible; but also that we must enjoy a particular kind of experience in order to cognize them. It suffices to know what a circle is to know that it is a figure, all the points in the boundary of which are equidistant from a single point. To grasp this, no particular kind of perceptual experience is necessary. In order, however, to understand what colours, scents and so forth are, we must enjoy perceptual experiences in the relevant sense modalities. Sensory qualities are sense-specific in that cognition of them requires the enjoyment of sensation that is definitive of a specific sense modality. The issue of whether sensory qualities are secondary or not is the issue whether the very character of the sensation that we enjoy when we perceive a sensory quality is itself possessed by the object perceived. Is, say, the quale of redness which we experience when we see a red-looking object, inherently and irreducibly present in red objects, such that its presence by itself constitutes them as red?

Two distinct reasons may be offered for giving a negative answer to this. First, even if physical objects possessed such qualia, that fact would not constitute them having sensory qualities such as colours and scents. This is because it is possible that objects should possess such sensuous features in a manner that was irrelevant to the generation of perceptual experiences in us. Since, however, objects necessarily possess those sensory qualities they are discriminated as having by competent observers in normal circumstances, and since necessarily sensory qualities are the basis in objects of such discriminations, such a possibility shows that the possession by physical objects of such qualia does not logically suffice for possession of the respective sensory qualities: possession of such qualia does not *of itself* constitute the possession of any sensory quality. It remains, perhaps, a priori possible that such qualia should be contingently identifiable with sensory qualities - if they are indeed the physical basis of sensory discriminations; for a decision that this is in fact contingently false we need to turn to empirical considerations. Perhaps, however, certain high-level theoretical considerations, of a kind which seem to have motivated Locke, and which are not nicely categorized as either empirical or a priori, may count against even such a possibility: for example, the irremediably non-mechanical nature of such supposed physical qualia doubtless conflicts with an involvement in perceptual transactions with the physical world that perhaps must be at least partly mechanical in nature; certainly one of the seventeenth century's chief objection to the postulation of sensory qualities as 'real' was that they are ultimately unintelligible.

The second a priori consideration goes further and denies the very possibility of sensory qualia being merely physically realized. From the fact that sensory qualia determine sense modalities it is concluded that any such quale is an inherent feature of sensation. Nothing which is an inherent, qualitative characteristic of sensation could also be a feature of an insentient physical object, as sensory qualities are supposed to be. For example, for colour to be instantiated is for a sentient subject to be visually conscious is a certain manner. On this view there is as much chance of a mere physical object being sensuously coloured as there is of the pin that pricks you feeling pain.

Since the issue of secondary qualities concerns the nature of sensory qualities, whereas the issue of primary qualities concerns the fundamental nature of matter as material substance, philosophers can be and have been in substantial agreement over which qualities are secondary, while yet being in serious disagreement over the list of primary qualities. Although, perhaps, the issue of the secondary status of sensory qualities is amenable to a priori philosophical reflection, since the issue of primary qualities concerns nothing other than the fundamental concepts of physics, it is doubtless hubristic to expect any a priori settling of the question.

Finally, it is worth mentioning that the disjunction between primary and secondary qualities is not exhaustive - many qualities of physical objects are clearly neither physically fundamental nor sensory.

Prior, Arthur Norman (1914-69)

Prior is most often thought of as the creator of tense logic. (Tense logic examines operators such as 'It will be the case that' in the way that modal logic examines 'It must be the case that'.) But his first book was on ethics, and his views on metaphysical topics such as determinism, thinking, intentionality, change, events, the nature of time, existence, identity and truth are of central importance to philosophy. Using methods akin to Russell's in his Theory of Descriptions, he showed that times, events, facts, propositions and possible worlds were logical constructions. For example, we get rid of events by recognizing among other things that to say that the event of Caesar's crossing the Rubicon took place later than the event of Caesar's invading Britain is to say that it has been the case that both Caesar is crossing the Rubicon and it has been the case that Caesar is invading Britain. The title of the posthumous work, Worlds, Times and Selves (1977), indicates the breadth and depth of his thought. He is also fun to read. He died at the age of fifty-four, at the height of his powers.

1 Life

Arthur Norman Prior was born in New Zealand. He entered the University of Otago in 1932, taking his BA in philosophy in 1935 and his MA in 1937. He studied under J.N. Findlay, working with him through Prantl's history of logic. Findlay made him an assistant lecturer in 1937, but after a year he left the university. The next eight years were spent in a wandering fashion, in Italy, France and Britain, in the New Zealand Air Force and as a freelance journalist. Prior's first marriage ended in 1943. Later that year he married Mary Wilkinson, and this marriage brought him great happiness and a collaborator in every aspect of his work. His writings, at first mostly theological but becoming increasingly philosophical, attracted notice, and in 1946 he succeeded Karl Popper as lecturer at Canterbury University College at Christchurch in New Zealand, becoming professor in 1952. His first book, *Logic and the Basis of Ethics*, was published in 1949. By this time Prior's interests had become centred on logic, and in 1951 he submitted to his publishers a work which eventually saw the light as *Formal Logic* in 1955. In this, as in his subsequent works, he used the logical symbolism invented in Poland by Jan Łukasiewicz. Prior had close ties with Polish logicians, lecturing in Warsaw in 1961. He was John Locke Lecturer at Oxford University in 1956. In 1959 he returned to England to take up a chair at Manchester University. He also taught for periods in Chicago and Los Angeles. In 1966 he became a Fellow of Balliol College, Oxford. *Past, Present and Future* and *Papers on Time and Tense* were published in 1967 and 1968. Oxford gave him a Readership with effect from October 1969, but it was in that very month that his sudden death occurred, while he was on a visit to Norway. Various of his works were prepared for publication after his death, most notably *Objects of Thought* in 1971.

2 Tense logic

Prior became a player on the international philosophical scene with his delivery of the John Locke Lectures at Oxford in 1956, published in 1957 as *Time and Modality*. In these he explored analogies between the logic of necessity and possibility and the logic of past, present and future. He had earlier written an article on the Greek philosopher, Diodorus Cronus, who tried to reduce necessity to what is and always will be and possibility to what either is or at some time will be. This involved the use of tense operators, most importantly *Pp* and *Fp*, 'It has been the case that *p*' and 'It will be the case that *p*', having the same syntax as *Lp* and *Mp*, 'It is necessary that *p*' and 'It is possible that *p*'. Thus began a whole new branch of logic, 'tense logic', which for some years Prior developed single-handedly. *Past, Present and Future* and *Papers on Time and Tense* together traced the way the theory had grown and displayed the state of the art at that moment. As with all his logical work, systems were not created, proofs constructed or definitions given just for their own sake - for elegance or economy - but because philosophical issues were always being addressed. He believed that to regard tensed propositions as basic to the expression of facts about time was to give an affirmative answer to the metaphysical question whether or not, as it has become fashionable to say, 'time is tensed'. His article 'Thank Goodness That's Over' (1959) contains his best argument for this position. He found that different choices of axioms in tense logic could be used to characterize time as unending, cyclical, discrete, continuous, and so on. The problem of determinism could also be given expression in formal terms, and philosophical views about ceasing to exist and coming into existence prompted modifications of tense-logical systems. Prior believed that propositions expressing facts about time in terms of relations between events or between events and times were reducible to propositions where time determinations were expressible by means of operators on sentences. This itself has implications for 'ontological' issues: we do

not need to rank times or events as 'basic particulars'. Again, Prior's use of simple '*p*' as opposed to '*Pp*' or '*Fp*' to represent present-tensed propositions led naturally to a 'redundancy theory' of the present, parallel in some ways to the redundancy theory of truth. It is raining now and it is true that it is raining if and only if it is raining (see Tense and temporal logic; Truth, deflationary theories of).

3 Truth

The use of tense operators, like that of modal operators, is a challenge to extensionalism: the material equivalence of *p* and *q* is not sufficient to guarantee that of *Fp* and *Fq* any more than that of *Mp* and *Mq*. Prior was uninhibited by extensionalist qualms, and equally uninhibited in his use of quantifiers to bind variables of categories other than that of names. He was accordingly happy to use quantificational formulas such as 'for every *p*' or 'for some *q*', following here the precedent of Łesniewski's 'Protothetic' (see Łesniewski, S. §4). As well as the tense and modal operators, he made room for expressions like 'Robinson says that' or 'Jones thinks that' which form sentences out of sentences. The verbs of propositional attitude he described as predicates at one end and connectives at the other: to make 'said that' into a proposition I have to put something like 'Winnie-the-Pooh' in front of it and something like 'bees like honey' after it. Equipped in this way Prior is able to go ahead and paraphrase 'Jones believes whatever Robinson believes' by 'For every *p*, if Robinson believes that *p*, Jones believes that *p*'. He is thus able to give an analysis of 'true' in terms of quantifiers binding propositional variables. 'What Pooh said is true' means, roughly, 'For some *p*, Pooh said that *p* and *p*'. Quine and Geach had frequently drawn attention to the analogies between the use of bound name-variables in quantificational formulas and the use of pronouns in natural languages. Since bound propositional variables correspond to sentences as bound name-variables do to names, Prior talks of them as 'prosentences'. This expression, first used by Prior in his article on the correspondence theory of truth in the Encyclopaedia of Philosophy edited by Paul Edwards, has since been used by Dorothy Grover and others to give the name 'prosentential theory of truth' to Prior's account of truth (see Truth, deflationary theories of).

4 Logical truth

Prior had something to say not only about truth, but also about logical truth. He could make a profound point in a short paper apparently designed more as fun than as a serious contribution to philosophy. A perfect example of this is 'The Runabout Inference Ticket' (1960). Empiricists seek protection from the embarrassment caused them by our knowledge of logical truths by claiming that this sort of knowledge is due entirely to conventions of language. The necessary truth of propositions of the form 'If *p*, then either *p* or *q*' rests, on this view, on the fact that we have chosen to adopt conventions for the use of 'if' and 'or' which make it 'true by convention'. Prior described a new convention. We could introduce a word 'tonk' into our vocabulary. The conventions for using 'tonk' determine that from any proposition '*p*' it is possible to infer a corresponding proposition '*p* tonk *q*', and from '*p* tonk *q*' it is possible to infer '*q*'. Putting these together it would be legitimate on the basis of these conventions to infer any proposition from any other proposition. Every proposition of the form 'If *p* then *q*' would be a logical truth. Something has gone wrong: Prior leaves it to the reader to work out what that is.

5 Propositional attitudes and intentionality

When he died, Prior left a manuscript entitled *Objects of Thought*. The book has two parts, corresponding to the two senses of the phrase which is its title: 'What we think' and 'What we think of'. What we think are in a sense propositions, but Prior's understanding of 'proposition' is determined by his view, already described, of the syntax of sentences like 'Pooh thinks that bees like honey'. He regards propositions as 'logical constructions'. What this means is that sentences which have as their grammatical subjects expressions which seem to designate propositions mean no more than equivalent sentences in which no expression plays this role. Thus 'The proposition that Paris is in Scotland is false' means no more than 'It is not the case that Paris is in Scotland'. This is not saying of a strange object called a 'proposition' that it has the equally strange property of not being the case: it is saying something about Paris and Scotland. Similarly, in Prior's view, 'The proposition that Paris is the home of vice is believed by McTavish' does not ascribe the property of being believed by McTavish to some proposition, but asserts that the property of being the home of vice in the eyes of McTavish belongs to Paris. The deep grammar of phrases like 'McTavish believes that' is the same as the surface grammar of 'in the eyes of McTavish': both belong to the category of adverbial phrases.

If what we think are in Prior's view logical constructions, what we think of are common-or-garden objects, rather than 'intentional' objects. One important consideration which led Frege and others to the view that in 'McTavish believes that Paris is the home of vice' the word 'Paris' designates an intentional object is that the sentence may change its truth-value if we substitute for 'Paris' another name of the same city. This supposed phenomenon was called by Quine 'referential opacity'. Prior, in 'Is the Concept of Referential Opacity Really Necessary?' (1963), maintained that the change of truth-value would occur only if the expression substituted for 'Paris' was a definite description, for example, 'the capital of France', and only then if the definite description had what Russell called 'secondary occurrence'. Substitution of names for names, when both are being used as names, does not, in Prior's view, lead in any case to change of truth-value. Nevertheless Prior is not an extensionalist, since he allows that substitution of coextensional predicates and materially equivalent propositions cannot always be made *salva veritate*. But Prior found difficulty in deciding when a name really was being used as a name, when McTavish's thought was directly about Paris, the city. Like Russell, he came to the view that few of our thoughts are directly about their objects. These are issues he debates in the second part of *Objects of Thought* (see Propositional attitude statements).

6 Logic and ethics

Prior was at one time an editor of *The Journal of Symbolic Logic*, and his output in and contribution to the field of formal logic was considerable, though impossible to summarize in an entry of this length. At the same time, the early interest he showed in ethics was never extinguished. His work in this field, as in others, is notable for his learning in respect of the history of the subject, particularly, in this case, in the area of the seventeenth- and eighteenth-century British moralists. A good sample of his ability to put logic to work in the service of ethics is his essay 'The Autonomy of Ethics' (1960), reprinted in the collection, *Papers in Logic and Ethics* (1976a).

Privacy

The distinction between private and public is both central to much legal and political thought and subject to serious challenge on philosophical, practical and political grounds by critics of the status quo. Privacy - the state of being withdrawn from the world, free from public attention, interference or intrusion - is a cherished social value that is being offered ever more protection. Increasingly, laws require people to respect the privacy of others: privacy is recognized as a fundamental right in international documents and national constitutions, and recent customs and social norms forbid intrusions that were once accepted. The concept of privacy is also widely abused: it has been used to justify private racial discrimination and state neglect of domestic violence, as well as social abdication of general economic welfare through laissez-faire *policies and the so-called privatization of social services. Critique of the public-private distinction is an important part of many critical theories, especially feminism and critical legal theory. These critics object that the public-private distinction is exaggerated, manipulable or incoherent.*

1 Privacy as a social value

The origin of privacy is controversial. Some maintain that the public-private distinction originated with the Greeks and that '[s]uch delineations could not have been made in the theocracies of the ancient Near East because in such cultures god-as-ruler permeates everything and no notion of the private is possible' (Wiltshire 1989: 8-9). Others argue that up to the middle of the sixteenth century 'privacy…was neither possible nor desired' (Stone 1977: 6), and that it first arose a few hundred years ago, as household size reduced and as houses began to be built with corridors and private spaces. Although it is unlikely that either of these assertions is fully correct, it also seems clear that different periods in history are likely to have had somewhat different concepts of privacy, just as different cultures today have different concepts.

Privacy is central to liberal thought - as a right the state guarantees to protect from interference by others or by the state itself. In Western democratic societies, privacy is generally seen as a state of being or a right enjoyed by an individual. Privacy is considered basic to a free and open society and crucial for individual development. It facilitates spontaneity and insulates the individual from social pressure to conform. It contributes to autonomy, creativity, the capacity to form human relationships and the development of personal responsibility. For this reason, liberal political philosophies - J.S. Mill's *On Liberty* (1859) is a prime example - nearly always seek to draw a line between that part of human behaviour which is private, and therefore not subject to legal or social control, and that part which is of public concern (see Law, limits of §4; Liberalism §§1-2).

Privacy is also extolled as essential to maintaining human relationships. Various collectivities, especially families, are sometimes said to require privacy or to be entitled to privacy. Unmarried heterosexual couples are often seen as deserving of a degree of privacy in order to be free to form a relationship. Lesbians, gay men and other sexual minorities have sought recognition of their relationships as alternative families entitled to privacy; sometimes this group-based approach has protected intimate relations more successfully than appeals to a notion of individual privacy.

2 Public protection of privacy

The concept of privacy as a legal right is of recent origin. In the USA it was introduced into the literature in 1890 by an influential law review article (Warren and Brandeis 1890). It received recognition as a constitutional right in the USA in 1965 in *Griswold* v. *Connecticut*, which established a privacy right for married couples to use birth control. This privacy right was found to attach to single people also and to protect an individual's access to abortion as well as to birth control (*Eisenstadt* v. *Baird* 1971; *Roe* v. *Wade* 1973). The right to privacy has also been recognized in major human rights documents such as the Universal Declaration of Human Rights.

Several competing state interests limit the protection given to privacy. Searches, seizures, involuntary blood and drug tests, and numerous other intrusions are allowed in the name of national security or crime detection. A major limitation upon privacy comes from competing rights, such as the freedom of speech and of the press (see Freedom of speech). In the USA, freedom of speech limits the protection given to 'public figures' against intrusions into privacy and limits defamation actions to cases in which the defamer acted 'maliciously' (*New York Times* v.

Sullivan 1964). Freedom of the press has been found to override the interests of a rape victim to remain anonymous, even when the victim reasonably fears that the publication of their name would cause them to be targeted for further abuse and violence (*Florida Star* v. *BJF, US* 1989).

Computer technology has heightened concern regarding the protection of privacy by radically increasing the possibilities for gaining information about others. Large quantities of information about a person can now be collected, stored, processed and retrieved at relatively low cost. Data protection laws are being developed and refined in many countries to deal with these issues. Computer bulletin boards raise privacy issues that are just beginning to emerge. The widespread use of computers by children has facilitated access to them by adult child molesters who may pose as children and eventually set up a rendezvous.

3 Abuses of the public-private distinction

The public-private distinction has been improperly used to justify social policies that maintain power relations and leave defenceless people exposed to conditions that, if recognized as a public concern, should seem unacceptable. For example, exploitation and abuses of employees long went unchecked and legislative efforts to protect workers were overturned by courts on the basis of *laissez-faire* policies grounded in large part on the notion that private property should not be subject to public control. Even today labour unions in many countries are restricted on the basis of a public-private distinction: many aspects of the work environment and decisions related to these concerns are removed from collective bargaining because such issues are said to involve private management discretion that should not be meddled with by the public.

Racism and discriminatory decisions based on prejudice were until recently defended as a private prerogative, not to be interfered with by the state. Even as US courts began to protect the rights of African-Americans, the public-private distinction was used to limit review of racial discrimination to instances in which ‘state action’ could be found. ‘Private’ discrimination was not forbidden by the Constitution. Notions of privacy continue to limit the scope legislators give to employment discrimination laws, often exempting employers in small, more private-seeming establishments. The British Race Relations Act (1965), which forbids discrimination by anyone serving ‘the public’, was found not to protect against discrimination by a so-called private club that chose members ‘by nomination and personal selection’ (*Race Relations Board* v. *Charter and Others*, UK 1973).

The supposed privacy of the family has shielded brutality and abuse from public scrutiny and redress. In many areas of the world a special exemption to the rape laws withdraws protection from women who are married to the man who forces sexual intercourse upon them, no matter how brutally he does so. Many criminal and civil laws against physical assault have similar exemptions when the victim is the wife or the child of the perpetrator. Where the laws do forbid violence within the family, notions of family privacy nevertheless often limit the effectiveness of the enforcement of these laws.

Of course, there are those who would defend these uses of the public-private distinction as properly protective of private property, personal choice and family privacy. One reason that privacy needs to be protected, they could argue, is that individual cases arise in which the urge to intervene will be great, yet overall in the long run, non-intervention is to be preferred.

A second kind of abuse of the public-private distinction occurs when there is slippage between the descriptive claim that something is either public or private and the normative claim that it should be treated as public or private. This slippage leads to circular arguments and to efforts to foreclose discussion of the advantages and disadvantages of the policy advocated.

4 Critiques of the public-private distinction

What some critics see as an abuse of the public-private system distinction, others see as a problem inherent in the distinction itself. Since everything is socially conditioned, there is no sphere that is wholly private - there is a public dimension to private affairs and vice versa. Moreover, the line that is drawn between public and private does not reflect a natural distinction but an ideological purpose. It mystifies inequalities in society by treating them as irrelevant to political equality. Marx, for example, saw the division between the private individual and the public citizen as part of the alienation of mankind under capitalism. The state was not the public bulwark against private oppression that liberal theorists supposed, but an agent of the ruling class.

Similar criticisms of *laissez-faire* capitalism were raised in the 1920s and 1930s by radical legal realists and others. The sphere of apparently free or private economic activity was dependent on legal rules created by the state, which thus structured and controlled power relations in society. Businessmen who called for an end to state regulation of the economy were inconsistent, because their own economic activity depended upon pro-business regulation.

The feminist critiques of the public-private distinction go further. Feminists point out that the public-private distinction is more than a distinction between the state and civil society, between the general interest and the particular interest, or between a person's public life as a citizen and private life as a self-regarding individual. It is also a distinction between men and women, between the public world of business and industry and the private, domestic world of the family. This gender association of private with women and public with men has important consequences for the role and status of women as well as for the particular meanings given to privacy (see Feminist political philosophy §§1, 7).

The legal realist critique of *laissez-faire* applies with equal force to arguments against state intervention in the family. The state structures domestic life through its family law provisions, as well as less noticeably through its policies regarding rape, employment discrimination, taxes, welfare benefits and childcare policies. Moreover, the public world of affairs - commerce, industry and so forth - is not separate from and opposed to the domestic world of the family; rather the two are inextricably interrelated (Olsen 1983). Carole Pateman has argued forcefully that the 'apparently impersonal, universal dichotomy between private and public' obscures the 'fact that patriarchalism is an essential, indeed constitutive, part of the theory and practice of liberalism' (Pateman 1983: 286)

Although many or most feminists might be said to accept privacy as such in that they, like others, appreciate solitude and would not want every aspect of their lives exposed to general public view, feminist criticism of the public-private distinction is more than just an objection to where the distinction is traditionally drawn and how it is used. Feminists challenge the way the line is drawn, the manner in which each term - public and private - is defined, and the basic dichotomous nature of the public-private distinction.

One way of understanding the gendered nature of privacy in Western thought is to consider that women are more closely associated with privacy but men are more assertive to claim a private realm for themselves. Women *are* privacy; they do not *have* privacy. Men as a group consider their interactions with women private, but as a group they also freely intrude upon the solitude of women, whether through street harassment or more gentle forms of imposition. This is a specific case of the general relationship between privacy and hierarchy. The hierarchically superior has privacy; the inferior does not. In order to have privacy, the inferior would have to exclude the superior in a way that is unnecessary for the superior.

Private language argument

Ludwig Wittgenstein argued against the possibility of a private language in his 1953 book Philosophical Investigations, where the notion is outlined at §243: 'The words of this language are to refer to what can be known only to the speaker; to his immediate, private, sensations. So another cannot understand the language.' The idea attacked is thus of a language in principle incomprehensible to more than one person because the things which define its vocabulary are necessarily inaccessible to others; cases such as personal codes where the lack of common understanding could be remedied are hence irrelevant.

Wittgenstein's attack, now known as the private language argument (although just one of many considerations he deploys on the topic), is important because the possibility of a private language is arguably an unformulated presupposition of standard theory of knowledge, metaphysics and philosophy of mind from Descartes to much of the cognitive science of the late twentieth century.

The essence of the argument is simple. It is that a language in principle unintelligible to anyone but its user would necessarily be unintelligible to the user also, because no meanings could be established for its signs. But, because of the difficulty of Wittgenstein's text and the tendency of philosophers to read into it their own concerns and assumptions, there has been extensive and fundamental disagreement over the details, significance and even intended conclusion of the argument. Some, thinking it obvious that sensations are private, have supposed that the argument is meant to show that we cannot talk about them; some that it commits Wittgenstein to behaviourism; some that the argument, self-defeatingly, condemns public discourse as well; some that its conclusion is that language is necessarily social in a strong sense, that is, not merely potentially but actually. Much of the secondary (especially the older) literature is devoted to disputes over these matters.

An account of the argument by the influential American philosopher Saul Kripke has spurred a semi-autonomous discussion of it. But Kripke's version involves significant departures from the original and relies on unargued assumptions of a kind Wittgenstein rejected in his own treatment of the topic.

1 The significance of the argument

The idea that a language might be private is explicitly canvassed in the second of Bertrand Russell's lectures 'The Philosophy of Logical Atomism', and Wittgenstein's argument, though possibly directed against his own earlier views in *Philosophical Remarks*, may originate in the sustained criticism of Russell which informs much of his writing.

Immediately prior to the *Philosophical Investigations*' discussion of private language, Wittgenstein suggests that the existence of the rules governing the use of words and making communication possible depends on agreement in human behaviour. This agreement includes people's reacting in similar ways to similar training, and exemplifies contingent 'very general facts of nature' which make particular concepts and customs possible and useful. Thus, for instance, one can train most children to look at something by pointing at it (whereas dogs look only at one's hand), and this enables us to attach meaning to the gesture of pointing and derivatives like signposts. The immediate function of the private language argument is to show that the possibility of linguistic rules and concept formation in general depends upon the possibility of such agreement.

But it has a further, connected, function. Motivating Wittgenstein's discussions of both mathematics and psychology is hostility to metaphysical absolutes, to the idea that we can find the world as it really is in the sense that any other way of conceiving it must be wrong (compare Wittgenstein 1953: 230). Both numbers and sensations provide especially tempting cases for philosophers, who are inclined to imagine that these are objects which force their identities upon us, our classifications of them and the rules governing the uses of their names being dictated to us in advance by the phenomena themselves. Wittgenstein makes precisely analogous points in his treatment of the two cases. In both, the underlying confusion is about how the act of meaning determines the future application of a formula or name.

With numbers, one temptation is to confuse the mathematical sense of 'determine' in which, say, the formula $y = 2x$ determines the numerical value of y for a given value of x (in contrast with y (2x, which does not) with a causal sense in which a certain training in mathematics determines that normal people will always write the same value

for *y* given both the first formula and a value for *x* (in contrast with creatures for whom such training might produce a variety of outcomes). This confusion produces the illusion that the outcome of an actual properly conducted calculation is the inevitable result of the mathematical determining, as though the formula's meaning itself were shaping the course of events.

In the case of sensations, the parallel temptation is to suppose that their natures are self-intimating - I seem to feel what they are directly, so that I need only give a name to one of them and the rules for the subsequent use of that name will be fixed on the spot. Wittgenstein tries to show that this is an illusion, that even that apparently most self-intimating of all sensations, pain, derives its identity only from a sharable practice of expression, reaction and use of language. Now if, say, pain were to force its identity upon me in the way described, then the possibility of such a shared practice, which in turn depends upon those general background facts of nature, would be irrelevant to the concept of pain. That is, if the real nature of part of the world were revealed to me in a single mental act of naming, as the private linguist supposes, then all subsequent facts would necessarily be irrelevant and the name could be private. The private language argument concludes that they could not be irrelevant, that no names could be private, and that the notion of having the real nature of the world so revealed is confused.

Such confusions underlie a range of articulated philosophical ideas and theories, without themselves being so articulated. The argument thus attempts, not to refute any particular theory, but to remove the motivation for involvement in a range of seemingly independent tasks, problems and solutions. Here are some frequently cited examples.

A still very common idea, found in Locke, is that interpersonal spoken communication works by speakers' translation of their internal mental vocabularies into sounds followed by hearers' re-translation into their own internal vocabularies (see Locke, J. §5). Again, Descartes considered himself able to talk to himself about his experiences while claiming to be justified in saying that he does not know (or not until he has produced a reassuring philosophical argument) anything at all about an external world conceived as something independent of them. And he and others have thought: while I may be wrong in my judgments about the external world, I am infallibly correct if they are restricted to my sensations. Again, many philosophers have supposed there to be a problem of other minds, according to which I may reasonably doubt the legitimacy of applying, say, sensation-words to beings other than myself (see Other minds). In all such cases, the implication is that my language could in principle be private: for these problems and theories even to make sense, the ability to share must be irrelevant to meaning and it must be conceivable that I am confined to my own case. (This suggestion is controversial: the usual charge is that such philosophers are committed to supposing that there actually is a private language. But this is not obvious, and the argument would be just as significant if all they are committed to is the supposition that their presupposed internal language, for all the difference it would make to its usability for self-communing, could be private.) This is especially clear in the case of Descartes, who must hold it possible to identify one's experiences inwardly, that is, without using any resources supplied by one's embodiment in an independently existing world, such as the concepts acquired in a normal upbringing. How is this identification to be achieved? This is the question considered in the next section.

2 The nature of the argument

The private language argument is usually identified with §§256-71 of *Philosophical Investigations*, a tightly-knit discussion of sensations, with §258 being especially important. But this discussion cannot properly be detached from the earlier sections of the book, despite commentators having frequently done just this. As important as the already-noted connection with the lengthy prior discussion of rule-following is the treatment of ostensive definition.

The argument proper is preceded by a preliminary discussion (§§244-55) in which Wittgenstein distinguishes two senses of 'private' and argues that natural languages (English, for example) are private in neither. The question then arises, could anything be a private language? He approaches this question by considering how a private language might be arrived at. It cannot be reached via the actual language we speak, for that is not private, and the attempt to convert it by thought experiment into a private one by simply suspending all expression of sensation and imagining the speaker just to name a sensation, as it were in a vacuum, merely raises the question of what this is supposed to consist in and what it is for. But to give private language enthusiasts a run for their money, Wittgenstein imagines himself in the position of establishing a private language for the purpose of keeping a

record of his sensations.

But he faces a serious impediment to discussing the matter at all: that doing so requires the mention of actions like ostensive definition, concentrating the attention, speaking, writing, remembering, believing, and so on, in the very process of suggesting that none of these can really be done in the circumstances under consideration. (This must be remembered in reading what follows, which in strictness should be constantly disfigured with scare quotes.)

He considers the idea that I simply *associate* a sign, say ‘S’, with a sensation by concentrating my attention on the sensation and saying ‘S’ to myself (the private analogue of ostensive definition), and points out that if this is to be a genuine definition it must establish a persisting connection between sign ‘S’ and that sensation: ‘"I impress [the connection] on myself" can only mean: this process brings it about that I remember the connection right in the future (§258)’.

This single remark has caused much trouble. Many have thought ‘I remember the connection *right*’ means ‘I use ’S’ only when I have S.’ This had the argument resting on scepticism concerning memory, and provoked the criticism that memory’s fallibility is neither more nor less a problem for a private linguist than a public one, so that the argument threatens both or neither. Wittgenstein’s defenders retorted that fallibility is no problem only where mistakes can be corrected; in the private case, there can be no checking of memories, hence no chance of correction, and consequently talk of correctness is inappropriate. The critics responded by arguing either that such checking is possible, or that correctness does not require checkability.

This interplay of criticism and defence characterizes much of the commentary on the argument. But it is beside the point. Both sides mistakenly assume the connection in question between ‘S’ and the sensation to be a connection of *truth*, so that remembering the connection right is a matter of making the judgment that I am experiencing S only in the presence of S. But the connection Wittgenstein says must be remembered is a connection of *meaning*. It can now be seen that the argument makes no appeal to the fallibility of memory.

Imagine I am a private linguist. I have a sensation, and make the mark ‘S’ at the same time, as one might in an ordinary case introduce a sign by ostensive definition. Now suppose that later, I use ‘S’ in judging that I am again experiencing the same sensation. What do I mean by ‘S’ on this second occasion?

It cannot be that I mean the sensation I am now experiencing, for this collapses the distinction between meaning and truth and removes the status of factual assertion from my judgment that I am experiencing S - it becomes at best a fresh ostensive definition. (Thus I cannot say informatively that my shirt is orange and with the same utterance explain what ‘orange’ means by exhibiting my shirt.)

Can it be rather that I mean the sensation I named ‘S’ on the previous occasion? That would presuppose that I had indeed succeeded in giving my sensation the name ‘S’, but this cannot just be assumed: for there to have been an ostensive definition of ‘S’, a technique for the use of ‘S’ must have been established, one which leads to my using ‘S’ in the same way as before. This, though, is just what is in question. What would using the sign in the same way be here? The same way as what? Wittgenstein’s earlier discussion of ostensive definition showed that there can be such definitions only where a place for them is already prepared - just pointing and making noises does not establish what sort of thing is being pointed at, even in the public world, and as a private linguist I cannot even do that but at best can only concentrate my attention. ‘S’ must be the name of a *sensation*, and the fact that I have had a sensation and simultaneously inwardly muttered ‘S’ does not suffice to make ‘S’ the name of that sensation. (To name a sensation is to name a *kind*, but what kind? A sensation may be classified in indefinitely many ways: ache, sensation-in-leg, sensation-at-time-*t*,….) And if one thinks a private linguist could remember the meaning of ‘S’ by remembering rightly the past correlation of ‘S’ with a certain kind of sensation, one presupposes what needs establishing: that there was such an independent correlation to be remembered. Fallibility of memory, even of memory of meaning, is neither here nor there: the point is that there has to be the right sort of occurrence in the first place to be a candidate for being remembered; and if there is not, no memory is going to create it. If, alternatively, we do not suppose that there is something to be remembered which is independent of the memory, then ‘what seems right to me is right’, that is, there is nothing to be right or wrong about. (These points are made in Wittgenstein 1953: 258-68.)

The conclusion is that it is impossible for a private linguist to establish and maintain a rule for the use of an expression, so that meaning is unobtainable in a private language. Only operating in a world independent of one’s

impressions of it, in which one's operations are thus in principle available for scrutiny, can provide the possibility of real correlations of signs with objects and consistency in the usage of those signs.

3 Related considerations

The argument as given is embedded in a collection of arguments, observations and reminders on the connected topics of the relations between expression and description of experiences, between mind and behaviour, and between self-knowledge and knowledge of others, concentrated mainly in §§243-315 of *Philosophical Investigations* but spreading into other sections and other works. This whole collection is sometimes referred to as the private language argument. But the question of private language is present in several of Wittgenstein's even apparently unrelated discussions, such as those of seeing-as (seeing a triangle as resting on its base, for example), and kinaesthesis, where the only available descriptions of the experiences involved which do justice to their contents make direct reference to a sharable world of public objects.

Central to his thought here is the belief that no one argument will suffice to eliminate the commitment to private language, for it is the result of various powerful illusions. One of these is the idea that one can study the nature of mental phenomena by introspection, as though this gave us direct and unmediated access to the truth-condition for, say, 'My neck is itching', a condition to which only I am privy (see Introspection, psychology of). In contrast, Wittgenstein argues, the nature of mental phenomena is grasped not by introspection but by examining 'language and the actions into which it is woven' (what he calls the 'language-game'), a publicly available practice of using words: with pain, this involves crying, complaining, comforting, administering analgesics and so on (*Philosophical Investigations*, §7).

Another source of the idea of a private language is that, where thoughts and sensations are concerned, there is in the normal first-person case no gap between truthfulness and truth. Philosophers are inclined to interpret this as a special epistemic authority about one's own mind, whose contents are hidden from others. Wittgenstein's treatment of this has been one of the most disputed parts of his discussion; he has been interpreted as suggesting that the lack of first-person uncertainty in utterances like 'My leg hurts' derives from their being not genuine reports of inner occurrences but sophisticated groaning. It is now a short (and often-taken) step to infer that this involves a commitment to supposing that there is nothing behind the outer behaviour, and thus to a form of behaviourism (see Behaviourism, analytic). Such oscillation between privacy and behaviourism, as though the former were the sole alternative to the implausibility of the latter, is typical of the bind philosophers get into in this area, so that they cannot see that the blocking of this route to private language involves the attempt to undermine assumptions common to both. These include such ideas as that witnessing a person's acts is being confronted with neutral behavioural data from which mentality must be inferred or constructed, and that dealing with other human beings is always a matter of hypothesis rather than of attitude and response. But Wittgenstein's view is that these ideas misconstrue the metaphorical inner/outer contrast; his rejection of this construal is not a denial of the reality of the inner.

4 Kripke's Wittgenstein

Saul Kripke's account of Wittgenstein's treatment of rules and private language has generated much second-order discussion of a kind notably different from that of Wittgenstein himself. This is often carried on without apparent concern for the question of whether Wittgenstein's own arguments are captured by Kripke's interpretation. Thus the phrase 'private language argument' has acquired a further sense in which it refers to the arguments as given by Kripke.

Kripke's interpretation resembles that given here in its emphasis on the dependence of the discussion of private language on that of rule-following. But Kripke (1982: 68) says, 'The impossibility of private language emerges as a corollary of his sceptical solution of his own paradox', one stated at *Philosophical Investigations* §201: 'No course of action could be determined by a rule, because every course of action can be made out to accord with the rule.' Apparently overlooking Wittgenstein's reference to this paradox as involving a misunderstanding, Kripke takes it to be a profound sceptical problem about meaning. He formulates this problem in two ways.

The first formulation is this: there is no fact in which someone's meaning something consists. The absence of this fact, in Kripke's view, leads Wittgenstein to abandon the explanation of the meanings of statements like 'Smith

meant addition by ‘plus’’ in terms of truth-conditions; instead, they get explained in terms of assertibility-conditions, which involve actual (not merely potential) community agreement. (Hence the claim that this is a ‘sceptical solution’: Wittgenstein is supposed to concede to the sceptic the absence of truth-conditions for such statements.) This agreement, on Kripke’s account, legitimizes the assertion that Smith meant addition by ‘plus’ despite there having been no fact of the matter, and it of course rules out the possibility of private language immediately (see Private states and language §4). This first formulation, though, relies on the assumption that we have some idea of what a fact is, independent of a statement’s being true; and one of the fundamental lessons of *Philosophical Investigations* is that there is no such idea to be had, that the only route to the identification of facts is via the (often not easily discerned) uses of the expressions in which those facts are stated. These uses give us the truth-conditions.

The other formulation of the problem is that there is no nexus between someone’s meaning something and their subsequent behaviour, so that, for example, my grasp of the rule governing the use of ‘plus’ does not determine that I shall produce a unique answer for each of indefinitely many new additions in the future. The impression that something is missing here, though, is a result of just that kind of confusion about determination identified in §1 above.

Kripke’s account is of great intrinsic interest, but despite the acuteness of some of its observations, as an interpretation of the private language argument it is thus deficient, especially because of his unargued reliance on ideas which Wittgenstein himself argued against. This has not deterred philosophers from using it, as Norman Malcolm’s earlier account was used, as a way of avoiding direct confrontation with Wittgenstein’s own text.

Private states and language

Something is 'private' if it can be known to one person only. Many have held that perceptions and bodily sensations are in this sense private, being knowable only by the person who experiences them. (You may know, it is often said, that we both call the same things 'green'; but whether they really look the same to me as they do to you, you have no means of telling.) Regarding the relation between private states and language two main questions have arisen:

(1) Could there be a 'private language', that is, a language in which a person communicates to themselves, or records for their own use, information about their own private states - this language being in principle incomprehensible to others, who do not know the nature of the events it is used to record. This question is primarily associated with Ludwig Wittgenstein.
(2) Can the nature of our private states affect the meaning of expressions in the public language, that is, the language we use for communicating with each other? Or must everything that affects the meaning of expressions in the public language be something which is itself public, and knowable in principle by anyone? Michael Dummett has argued that we must accept the second of these alternatives, and that this has far-reaching consequences in logic and metaphysics.

1 Epistemic privacy

The epistemically private is defined as whatever can in principle be known to one person only. The words 'in principle' are intended to exclude all cases in which something is in fact known to only one person, though it could be known to more. The only items that have generally been taken to be epistemically private in this very demanding sense are conscious mental states, primarily perceptual states and bodily sensations of a conscious subject, on the plausible grounds that nothing that a person can do can possibly give them a view of another's conscious states, but only of their bodily states and behaviour.

However, these grounds for taking such states to be epistemically private cannot by themselves decide the question whether there actually are any epistemically private items in the sense defined. Privacy, as we have seen, is defined in terms of what cannot be known to another, and from the fact that another cannot *experience* my headache it does not immediately follow that they cannot *know* what it is like. That must also depend on our understanding of knowledge, in particular on whether we can allow that what cannot be directly experienced by someone can nevertheless in some other way be known by them.

Discussion of this complex question is beyond the scope of this entry, in which it can only be remarked that some views of the nature of knowledge are not wholly unfavourable to the idea that the contents of another's consciousness may sometimes be known (see Reliabilism; Other minds). Here it will be assumed that there are epistemically private states of the type commonly suggested.

We have spoken above of *two* questions concerning private states and language, and it is important to realize that, although related, they must be considered separately if clarity is to be achieved. To see this, the reader should consider the following. An impressive argument (discussed in §§2-3) for denying that private states can play any part in the semantics of the language that we speak with each other begins from the premise that the nature of one's private states is unknown to anyone else, and concludes that if it in any way affected the meanings of our words we would not know what any other person meant, and so could not speak this language with mutual understanding - which is then taken to be absurd. As it stands this argument clearly has no application whatever to the first question, the possibility of a private language. For a private language is understood to be one in which no other speaker is involved, so that the fact that one's private states are unknowable to others is entirely beside the point. To reach the analogous conclusion it would have to be said that private states are unknowable not just to others but to their owners as well, and this much stronger claim clearly requires further and altogether different argument. Conversely, we shall also see (§4) that it is possible to argue against the feasibility of a private language using a line of thought that may not apply to the question about the public language.

2 Acquisition and manifestation

Two arguments now frequently offered for the conclusion that private states can play no role in determining the meaning of any expressions of our (public) language are known as the acquisition and manifestation arguments. Each assumes that, in so far as there exists a language in which we communicate with each other, the expressions of that language must be used in the same sense or meaning by all of us. The acquisition argument then asks how this state of affairs could come about; the manifestation argument asks how we could tell that it obtained.

Suppose that there are expressions of this public language whose meaning depends on the nature of certain of the private states of competent speakers. (Plausible examples are colour words - it might well be thought that what I mean by ’red’ depends at least in part on how certain things look to me - and words for sensations such as ’pain’.) Now consider the situation of language learners acquiring an understanding of one such expression. *Ex hypothesi* this means that they must come to use it in connection with private states of their own of the same kind as those already associated with it by competent speakers; but since these states, being private, are not accessible to the learners, how can they hit on the right meaning? Learning the language would call for an absurdly improbable series of lucky guesses.

The manifestation argument views the process from the other side: how are the teachers to tell that the learners have learnt their lesson correctly? How can the learners show that they have grasped (’manifest their grasp of’) the right meaning? For to grasp the right meaning is to connect with the expression particular private states rather than others; and because they are private that is something which the teachers are in principle unable to check. We could never know, in the case of these expressions, what any other speaker means by them.

We should note that neither of these arguments makes appeal to verificationism (see Meaning and verification) - both trade on the idea of what can be *known*, rather than of what is *meaningful*. The importance of this is not just that they avoid inheriting verificationism’s weaknesses; it is also that otherwise they could not, without deep suspicion of circularity, be used to lead to a conclusion not altogether unlike verificationism - as they in fact have (see §5).

3 Responses to these arguments

One response, hinted at in §1, would be to deny that we have any states which are in principle unknowable to others. In view of the history of such sceptical debates this seems unlikely to lead to anything decisive.

A possible reply to the acquisition argument is as follows. Perhaps human beings naturally assume that others, when in broadly similar circumstances, experience inner states similar to those which they themselves experience. If that is so, and if the assumption is in most cases correct, then the problem posed by the acquisition argument can be answered. For since on this hypothesis the learner’s private states resemble those of the teacher (when, for example, both are in the presence of the kind of object we call ’red’) and are believed by both parties to do so, there is no difficulty in seeing how the learner can come to associate with the word ’red’ private visual states which are of the same kind as those which the teacher associates with it.

But this does not settle the issue. For one thing, it makes no reply to the manifestation argument. For even if successful learning has occurred, how is anyone to tell? The teacher and the erstwhile learner have no way of knowing that they now mean the same. And if, as is often said, understanding someone is knowing what they mean, then they don’t understand each other - contrary to the hypothesis that they are speaking a mutually intelligible language.

It is not obvious, however, that understanding someone does require knowledge of their meaning, if knowledge is taken to be more than confident true belief, as it nearly always is (see Knowledge, concept of §2). For if your words express a certain thought, and I rightly and confidently believe that that is what they express, and so respond appropriately, it seems that everything we want of understanding has been achieved, and the additional demand for knowledge begins to look arbitrary.

Still the matter is not settled, for it may be replied that even if knowledge is not a necessary condition of understanding, nonetheless we *do* know what others mean by their words; therefore any theory which allows private states an essential role in semantics must be wrong, since it is committed to denying that we have such knowledge.

That commitment cannot be disowned, since it follows immediately from the definition of privacy, but it may be

less damaging than it at first looks. Perhaps the claim to knowledge in this case, in so far as it implies the capacity to give good reasons for what we claim to know, is indeed dubious. Such a view is controversial, but certainly not obviously untenable. The idea that some of our most basic beliefs are produced by a psychological mechanism which is non-rational, in the sense that its operations are quite independent of any capacity we may have to *give reasons* for the beliefs it produces, has a reputable history (see for instance Hume, D.). To enable it to act successfully any animal, including ourselves and our ancestors, needs a reliable and rapid way of forming beliefs about its environment; so our basic belief-forming mechanisms cannot rest on reasoning, which is too slow and uncertain. And if a belief was not formed by reasoning there is little ground for thinking that it must nonetheless be certifiable, retrospectively, by rational argument, since it is not clear what additional practical benefit that would confer.

It is arguable, therefore, that the appeal to the threat of scepticism yields no decisive proof of the inadmissibility of private states in the semantics of public language.

4 The approach via rule-following

The question may also be viewed from another direction. Recent discussion of Wittgenstein's writings about rules (see Meaning and rule-following) has lead some (eminently Saul Kripke 1982) to suggest that the notion that two items are of the same kind can only have meaning against the background of a consensus in usage. This principle gives rise to the following argument.

Signs have meaning only because they are used in accordance with rules. So if anything plays an essential role in determining the meaning of a sign it must be capable of playing this role consistently, that is, in the same way on the various occasions on which the sign is used. Therefore private states can play an essential role only if it can be said that the same kind of private state was experienced on different occasions. But that, according to the above principle, can be so only if there is a communal practice with regard to these items among a number of speakers. And there can be no such communal practice - precisely because they are private. It follows that they play no part in the determination of meaning.

The 'consensus-principle', once accepted, instantly defeats the possibility of a private language, if that be understood as a language which of necessity only one person can speak. But that does not mean that it immediately dismisses private states from any position in the semantics of public languages. For if one can have true beliefs about another person's private states (as perhaps one can, so long as the hypothesis advanced at the beginning of §3 remains unrefuted) then there can be such a thing as agreement about these states, and even disagreement, at least where insincerity is suspected. And then if this is held not to satisfy the demand for communal practice, it needs to be explained why the consensus required should need to be based on mutual knowledge rather than just confident belief - no easy task, since it has not proved easy convincingly to establish *any* form of the consensus principle.

5 Further consequences

This question has not normally been pursued for its own sake, but rather for that of its alleged consequences. M.A.E. Dummett, having concluded that a speaker's grasp of the meaning of a sentence must consist in their potential for outward, publicly accessible behaviour, tentatively suggests a further conclusion: it must consist in the capacity to recognize whatever state of affairs it is that makes the sentence true, in other words to tell that it is true, if and when it is. We can grasp no meaning, and so have no grasp of truth, beyond what we can in principle recognize as true; and it is this which is held to define antirealism and require the abandonment, characteristic of intuitionist mathematics, of the law of excluded middle as a generally valid logical principle.

The response to this train of thought must depend on the answers to a number of questions. Is it clear that the recognition of the fact that the truth conditions of a sentence obtain is the only (publicly accessible) way to demonstrate ('manifest') understanding of it? Is it even clear that the act of recognizing that certain conditions obtain *is* in the required sense publicly accessible? This cannot just be assumed. Recognition is an intensional state, since one can recognize the fact that *p* without recognizing the fact that *q*, even if these two facts always obtain together; we are therefore lead into the difficulties connected with such states, in particular the question whether they can be captured in purely physical behaviour (see Intensionality;Intentionality §2).

But neither should it be assumed that problems about meaning and understanding are easily resolved, or Dummett's conclusions easily avoided, if we are allowed the contrary assumption, that private states may be given a role in semantics. For that it is still too unclear what kinds of private state there are, and what their role could be, and hence what difference it makes if we admit them.

Probability theory and epistemology

The primary uses of probability in epistemology are to measure degrees of belief and to formulate conditions for rational belief and rational change of belief. The degree of belief a person has in a proposition A is a measure of their willingness to act on A to obtain satisfaction of their preferences. According to probabilistic epistemology, sometimes called 'Bayesian epistemology', an ideally rational person's degrees of belief satisfy the axioms of probability. For example, their degrees of belief in A and $-A$ *must sum to 1. The most important condition on changing degrees of belief given new evidence is called 'conditionalization'. According to this, upon acquiring evidence E a rational person will change their degree of belief assigned to A to the conditional probability of A given E. Roughly, this rule says that the change should be minimal while accommodating the new evidence. There are arguments, 'Dutch book arguments', that are claimed to demonstrate that failure to satisfy these conditions makes a person who acts on their degrees of belief liable to perform actions that necessarily frustrate their preferences. Radical Bayesian epistemologists claim that rationality is completely characterized by these conditions. A more moderate view is that Bayesian conditions should be supplemented by other conditions specifying rational degrees of belief.*

Support for Bayesian epistemology comes from the fact that various aspects of scientific method can be grounded in satisfaction of Bayesian conditions. Further, it can be shown that there is a close connection between having true belief as an instrumental goal and satisfaction of the Bayesian conditions.

Some critics of Bayesian epistemology reject the probabilistic conditions on rationality as unrealistic. They say that people do not have precise degrees of belief and even if they did it would not be possible in general to satisfy the conditions. Some go further and reject the conditions themselves. Others claim that the conditions are much too weak to capture rationality and that in fact almost any reasoning can be characterized so as to satisfy them. The extent to which Bayesian epistemology contributes to traditional epistemological concerns of characterizing knowledge and methods for obtaining knowledge is controversial.

1 Degrees of belief and probability

We ordinarily make a tripartite distinction among believing *Q*, believing not-*Q*, and suspending belief with respect to *Q*. Advocates of subjective probability think that beliefs come in more finely graded degrees. They further claim that rationality requires that degrees of belief satisfy the probability calculus and change in accord with a rule called 'conditionalization'. The classic sources for this view, Ramsey (1931), de Finetti (1972) and Savage (1954), argued that beliefs failing to conform to the probability calculus lead to actions that frustrate the believer's goals and for that reason a rational person will attempt to bring their degrees of belief into line with the probability calculus (see Ramsey, F.P. §2).

The degree to which someone believes that *Q* is manifested in their tendency to act on that belief. For example, if Arabella wants to get downtown by 5 p.m. and has a greater degree of belief that she will get downtown by 5 if she takes the train than if she takes the bus she will, other things being equal, take the train. One suggestion for measuring degrees of belief is in terms of the prices one is willing to pay for gambles. A simple gamble on *Q* is one in which $1 is paid if *Q* and nothing if not *Q*. Suppose that Arabella is willing to either buy or sell (in which case she is committed to pay the buyer of the gamble $1 if *Q* and nothing if not *Q*) a simple gamble on *Q* for $*x*, where $0 \leq x \leq 1$. In this case $*x* is the fair value of the gamble for Arabella and her degree of belief in *Q* is *x*. Advocates of subjective probability claim that an ideally rational person will assign degrees of belief to all propositions expressible in their language.

Nevertheless, measuring degrees of belief by willingness to pay for gambles is problematic. Experimental psychologists have accumulated evidence that seems to show that the value a person assigns to a gamble is dependent on how the gamble is described, on context, and is unstable (Kahneman, Slovic and Tversky 1982). Further, measuring degrees of belief in terms of gambles unrealistically assumes that the believer attaches no value (positive or negative) to gambling as such, that monetary gain corresponds to gains in utility, and that considering buying a gamble does not change one's degree of belief. These problems are not fatal since more sophisticated ways of measuring degrees of belief have been developed that do not depend on these assumptions. But even if there is a way of accurately measuring exact degrees of belief when they exist it is not plausible that we have exact

degrees of belief in most propositions. Most people would be unwilling to assign a fair value to a gamble. Usually the amount we would be willing to pay for a gamble is less than the amount at which we would sell it. These considerations have led to proposals for representing degree of belief in terms of intervals or more complicated structures (Levi 1980). For the most part these complications will be ignored here.

Degrees of belief that conform to the probability calculus are called 'subjective probabilities' since they are relative to believers. To satisfy the probability calculus a function P(*A*) (the probability of *A*) on a set of sentences (closed under negation and conjunction) must satisfy the consequences of the following axioms:

(1) $0 \leq \mathrm{P}(A) \leq 1$
(2) P $(A) = 1$ if *A* is logically true
(3) $\mathrm{P}(A \vee B) = \mathrm{P}(A) + \mathrm{P}(B) - \mathrm{P}(A \mathbin{\&} B)$

Degrees of belief that satisfy the probability calculus are said to be 'coherent'. Psychologists have accumulated evidence that shows that people's degrees of belief are typically not coherent. For example, subjects in experimental studies frequently assign a higher probability to a conjunction $Q \mathbin{\&} R$ than they do to *Q* in violation of the probability calculus (Kahneman, Slovic and Tversky 1982) (see Rationality of Belief). The failure of beliefs to be coherent is not an objection to subjective probability since coherence is a normative notion. Advocates of subjective probability think coherence is a norm for degrees of belief in the way that logical consistency is a norm.

Among the more important arguments for the claim that rationality requires coherence is one based on 'the Dutch book' theorem. A Dutch book is a set of gambles such that one who takes the gambles suffers a net loss no matter what. For example, if someone has degrees of belief $\mathrm{P}(Q) = 0.6$ and $\mathrm{P}(-Q) = 0.6$ then they will exchange $.6 for a gamble on *Q* that pays $1 if *Q* and nothing otherwise, and $.6 for a gamble on $-Q$ which pays $1 if $-Q$ is true and nothing otherwise. They cannot win both, so no matter whether *Q* is true or false they will lose $.2. It can be proved that satisfaction of the probability calculus is necessary and sufficient for not being subject to this kind of Dutch book. This establishes that rationality requires coherence only if rationality requires immunity from Dutch books, which is not obvious.

2 Changing degrees of belief

Suppose that Arabella initially has degrees of belief P(*A*), P(*B*) and P($A \mathbin{\&} B$) and that $\mathrm{P}(A) \neq 0$ and then changes the degree of belief she assigns to *A* to $\mathrm{P}'(A) = 1$. Conditionalization says that she rationally ought to change the degree of belief she assigns to *B* to $\mathrm{P}'(B) = \mathrm{P}(B|A)$. P($B|A$) is the *conditional probability* of *B* on *A* and is equal to $\mathrm{P}(A \mathbin{\&} B)/\mathrm{P}(A)$. For example, if the initial degrees of belief are $\mathrm{P}(M) = 0.5$, $\mathrm{P}(W) = 0.4$, $\mathrm{P}(U) = 0.1$ (*M* is the proposition that Colonel Mustard committed the crime, *W* is the proposition that Mrs. White did it, and *U* that Professor Plum did it), then when Holmes discovers that Colonel Mustard is innocent, conditionalization prescribes that his new degrees of belief should be $\mathrm{P}'(W) = \mathrm{P}(W|-M) = 0.8$ and $\mathrm{P}'(U) = \mathrm{P}(U|-M) = 0.2$. These changes seem reasonable since they involve the least change in degrees of belief required to accommodate the new information while maintaining coherence.

An important rule for calculating conditional probabilities is Bayes' theorem (after Thomas Bayes, who used it to calculate the probability that the stars are distributed randomly). Suppose that someone assigns degree of belief P(*H*) (the prior probability of *H*) and conducts an experiment *E* with possible outcomes *e* and $-e$. Suppose also that they assign degrees of belief P($e|H$) and P($e|-H$). Then the conditional probability P($H|e$) is given by Bayes' theorem:

$$\mathrm{P}(H|e) = \frac{\mathrm{P}(H) \times \mathrm{P}(e|H)}{\mathrm{P}(H) \times \mathrm{P}(e|H) + \mathrm{P}(-H) \times \mathrm{P}(e|-H)}$$

To apply Bayes' theorem one needs prior probabilities P(*H*), P($-H$) and likelihoods P($e|H$), P($e|-H$). The likelihoods are usually thought of as deriving from statistical or theoretical information about probabilities. The prior probabilities are the believers' initial degrees of belief. Their status is controversial and has received much discussion some of which will be summarized later. As an example, suppose that a physician assigns the prior probability $\mathrm{P}(D) = 0.3$ to the hypothesis that a patient has a certain disease. Suppose that there is a test for the disease with outcomes *e* and $-e$ such that $\mathrm{P}(e|D) = 0.9$ and $\mathrm{P}(e|-D) = 0.2$. If the test is conducted and yields result *e* then according to the rule of conditionalization the physician's new degree of belief $\mathrm{P}'(D) = \mathrm{P}(D|e)$,

which by Bayes' theorem is 0.65.

Not all changes in degrees of belief are initiated by changes from an intermediate value to 1. Richard Jeffrey (1983) proposes a rule, 'Jeffrey Conditionalization' (JC), to accommodate such changes. If one changes the degree of belief assigned to *A* from P(*A*) to $\mathrm{P}'(A)$ then one should change the degree of belief assigned to *B* from P(*B*) to

(JC) $\mathrm{P}'(B) = \mathrm{P}'(A) \times \mathrm{P}(B|A) + \mathrm{P}'(-A) \times \mathrm{P}(B|-A)$

Conditionalization is the special case of JC in which $\mathrm{P}'(A) = 1$ (and $\mathrm{P}'(-A) = 0$). So, for example, if Arabella changes her degree of belief in *M* to 0.7, the degrees of belief she assigns to *W* and *U* should be 0.24 and 0.06. An analogue of Bayes' theorem can be derived to calculate how degrees of belief should change by JC.

A further suggested constraint on rational degrees of belief is a principle, called 'Reflection', that concerns attitudes towards future beliefs (van Fraassen 1984):

Reflection: $\mathrm{P}_t(Q|\mathrm{P}_{t+x}(Q) = b) = b$

According to Reflection, on the condition that a person assigns a degree of belief at time $t + x$ to *Q* of *b* they ought to assign a degree of belief at time *t* to *Q* of *b*. The principle expresses the idea that one should consider her future degrees of belief as being formed rationally on the basis of accurate evidence. Of course, if someone believes that for some reason the beliefs that she will have at $t + x$ are not formed rationally or accurately then it would seem that rationality may require departures from Reflection. For example, if one knew today that tomorrow one would be a subject in an hypnosis experiment and caused to believe that the earth is flat, that would provide no reason to believe today that the earth is flat.

David Lewis (1986) proposed another constraint on rational belief that connects beliefs about objective chances with degrees of belief.

(PP) $\mathrm{P}_t(Q|\mathrm{ch}_t(Q) = x \;\&\; E) = x,$

where $\mathrm{ch}_t(Q)$ is the chance or objective probability at time *t* of *Q*. Objective probabilities are objective features of reality independent of our beliefs. There is controversy concerning how to construe objective probabilities. Among the proposals are that they are irreducible, that they are hypothetical frequencies (van Fraassen 1980), that they are actual frequencies, and that they are determined by the best fitting theory of the world (Lewis 1994) (see Probability, interpretations of). In any case, PP says that the degree of belief one has at *t* in *Q* given the condition that the chance of *Q* at *t* is *x* and other admissible information *E* is itself *x*. To a first approximation *E* is admissible with respect to *Q* if *E* provides no information about how chance events at or after *t* will turn out. We apply PP when we assign a degree of belief of 0.5 to the event of the coin landing heads when flipped, given that we believe that the coin is fair. In situations where one does not know the objective chance of an event *e* but assigns degrees of belief to exclusive and exhaustive hypothesis concerning that chance, PP can be used to provide the conditional degrees of belief of *e* given the various hypotheses. In the example of Bayes' theorem described above, the degrees of belief P($e|D$) and P($e|-D$) may derive from applications of PP. By linking objective chances and degrees of belief, PP grounds a Bayesian epistemology of objective chances. Exactly why PP should determine degrees of belief in chance events has not received much discussion.

There are Dutch book arguments for conditionalization, JC, and Reflection. The Dutch book argument for JC establishes that if a person places a value on conditional gambles (a conditional gamble is one that is in effect only if a condition is satisfied), and changes their degrees of belief in conformity with any rule other than JC, they will be susceptible to a Dutch book by a bookie who knows their rule.

The Bayesian principles of rationality concerning belief are part of a more general account of rationality connecting belief, preference and decisions called 'Bayesian decision theory'. In Bayesian decision theory decisions are seen as analogous to gambles in which the consequences of a decision depend on possible states of nature. The degree to which a decision-maker values a consequence *c* is its 'utility' $u(c)$. If we assume that a person has sufficiently many degrees of belief then utilities can be measured in terms of choices among gambles. If someone prefers c_1 to anything else and prefers anything else to c_n and is indifferent between a gamble in which they obtain c_1 with probability *p*, and c_n with probability $1 - p$ (according to their degrees of belief) then

$u(c) = p$. The key principle of Bayesian decision theory is that one selects a decision from among the possible alternatives that maximizes expected utility. The expected utility of a decision is given by:

$u(d) = \Sigma \mathrm{P}(h_i) \times u(c_i)$.

The set $\{h_i\}$ is an exclusive and exhaustive set of states of nature, the P(h_i) are the decision-maker's degrees of belief, and the $u(c_i)$ are the utilities the decision-maker assigns to the consequence c_i of their doing *d* when h_i obtains (see Decision and game theory).

The view that rationality requires that beliefs cohere, that they change by conditionalization, and that decisions obey the maximum expected utility rule form the core of 'Bayesian epistemology' (Reflection and PP are attractive additions but have not received as much discussion). Bayesian epistemology does not provide traditional analyses of knowledge or justification but it does describe ideals of synchronic and diachronic rationality. Some advocates think of it as supplanting, and others as supplementing traditional epistemology.

One issue that arises within Bayesian epistemology involves the relationship between degrees of belief and other epistemological concepts. An issue that has received much discussion is acceptance. Epistemologists mean a number of different things by 'acceptance' although there seems to be agreement that someone who accepts a proposition is making a commitment to defend its reasonableness. Acceptance is usually thought of as rationally requiring closure under logical consequence and conjunction. If one accepts $h_1, \ldots, h_n$ then one rationally should accept every consequence of their conjunction. One proposal for connecting subjective probability and acceptance is rule R: one should accept *h* if $\mathrm{P}(h) > r$ (where *r* is a threshold value close to 1). But this suggestion immediately leads to 'the lottery paradox'. Suppose that $r = 0.99$ and that a fair lottery has 1,000 tickets. The acceptance rule implies that one should accept each statement $-hk_i$ that says that ticket k_i will not win (since $\mathrm{P}(-hk_i) = 0.999$). But one knows that one of the tickets will win, so one ends up accepting a contradictory statements. Various responses to the paradox have been proposed (see Paradoxes, epistemic §1).

3 Bayesian epistemology and scientific method

Support for the Bayesian approach to epistemology comes from the fact that various features of scientific method follow from Bayesian principles (Rosenkrantz 1977; Earman 1992) (see Confirmation theory; Inductive inference; Scientific method). For example, a natural measure of the extent to which evidence *e* confirms hypothesis *H* is $\mathrm{P}(H|e) - \mathrm{P}(H)$. It is easy to see from Bayes' theorem that the greater the ratio $\mathrm{P}(e|H)/\mathrm{P}(e|-H)$ the more *e* confirms *H*. The conditional probabilities P($e|H$) and P($e|-H$) often measure how well the two hypotheses explain *e*. So Bayes' theorem endorses the principle that evidence confirms a hypothesis to the extent that the hypothesis outperforms its competitors in explaining the evidence. A related consequence of Bayes' theorem is that the greater the difference between P($e|H$) and P($e|-H$) the more the result of the test confirms one or the other hypothesis. In other words, the more severe the test the more the confirmation.

The Bayesian approach also rationally motivates experimentation. The uncertainty relative to an inquirer of a set of hypotheses $\{h_k\}$ is measured by the entropy of the probability distribution over the h_k; entropy $\{h_k\} = \Sigma \mathrm{P}(h_k) \log \mathrm{P}(h_k)$. Entropy is greatest when all the h_k are assigned equal probability and least when one of the hypotheses is assigned a probability of 1 and the rest 0. An inquirer would like to reduce the entropy of their probability distribution since that brings them closer to certainty. It is a consequence of the probability calculus that any experiment E that has an outcome *e* such that $\mathrm{P}(e|h_i) \neq \mathrm{P}(e|h_k)$ for $i \neq k$ has a positive expected value of reducing entropy. If E has outcomes which differentiate among the h_k and if outcomes of repetitions of E are independent given the h_k then it follows that the inquirer can expect that as they continue to experiment, the entropy will continue to decrease to its minimum; that is that they will eventually assign a probability of 1 to one of the hypotheses. Further, if the probabilities P($e|h_k$) reflect the actual frequencies that would be obtained on independent repetitions of E then it can be shown that they can expect to assign a probability of 1 to the true hypotheses.

While most epistemologists accept true belief as the goal of rational inquiry, this claim has recently been criticized as mistaken or unjustified (Stich 1992). An interesting by-product of the Bayesian theory of experimentation can also be used to provide a justification of the instrumental value of acquiring true belief (Loewer 1995).

4 Criticisms of Bayesian epistemology

There is little doubt that aspects of scientific method can be illuminated by the Bayesian framework. But it is much less clear either that Bayesian epistemology provides satisfactory answers to traditional epistemological questions or that the Bayesian account of rationality is cogent. The claim that the Bayesian account of rationality is correct has been challenged by attacking the arguments that rationality requires coherence and conditionalization and by attacking the relevance of the Bayesian account of rationality.

The Dutch book argument has been criticized by arguing that mere susceptibility to Dutch books does not make one irrational. A person who thinks that their beliefs are not coherent can refuse to buy or sell gambles and thus avoid Dutch books. The Dutch book argument for conditionalization is even less persuasive. The argument establishes only that someone who conforms to a rule for changing beliefs must conform to conditionalization to avoid Dutch books. But it is not clear that rationality requires that belief-change conforms to a rule. In fact, it seems that at least on some occasions we change our beliefs without conforming to any rule and that it is rational to do so. For example, when one learns of a new theory to which one had not previously assigned a degree of belief, it may be appropriate to reassess certain other degrees of belief. But it is hard to see how there could be a plausible rule in this situation specifying how one should change those degrees of belief.

The most disturbing objection is that the Bayesian ideal is epistemically irrelevant to us because people have, at best, few exact degrees of belief. Further, it is practically impossible to make sure that one's degrees of belief are coherent or that they change by conditionalization. Bayesian epistemologists have attempted to deal with the first problem by changing their account to represent beliefs by sets of probability distributions. Coherence can be identified with a set of coherent degrees of belief. Whatever the plausibility of this suggestion for representing beliefs it makes the second problem even worse. This problem is that it will generally be impossible to determine whether an assignment of degrees to a collection of sentences is coherent. In fact there is no computationally effective method for achieving coherence in general since coherence requires assigning logically equivalent sentences the same degree, and never assigning a higher degree to *A* than to *B* if *A* logically implies *B*. There is no computationally effective method for determining in general whether or not *A* logically implies *B*.

The Bayesian response to these objections is to grant that, even if coherence and conditionalization are standards we cannot generally meet, they are ideals we should strive to approximate.

Whether or not conformity to Bayesian principles provides an epistemically valuable ideal, Bayesian epistemology is certainly incomplete as an account of rational belief. Specifically, there are at least three places at which it requires supplementation.

(1) If $\mathrm{P}(A) = 0$, then P($B|A$) is undefined, so conditionalization on propositions with probability 0 is undefined. But it seems plausible that sometimes a rational person may change their degree of belief in a proposition from 0 to 1 (or an intermediate value). There are some suggestions in the literature for how to extend conditionalization to this case.
(2) There is no constraint on the conditions under which propositions can initiate conditionalization or Jeffrey conditionalization. For example, someone's beliefs can conform to Bayesianism even though they change their probabilities on the basis of unreliable hunches. Rationality apparently requires restrictions on the changes that can initiate changes. Empiricism suggests that the inputs should be restricted to reliable observations. However, it seems dogmatic to restrict all changes to those initiated by observations. Sometimes reflection on a problem or thinking up a new hypotheses initiates changes in degrees of belief in ways that are considered rational. Bayesians have yet to produce a compelling account of rationally legitimate belief-changes.
(3) Coherence does not preclude assigning a high degree of belief to the claim that the earth is flat or taking the observation of green emeralds observed before time *t* as evidence for all emeralds being 'grue' (that is, green if observed before *t* and blue otherwise). This has been called 'the problem of the priors' since subjective Bayesian puts no constraints on the prior probabilities P(h_i) that enter as inputs into Bayes' theorem. Some Bayesians point to certain 'convergence theorems' to mitigate this problem (Savage 1954). According to one convergence theorem, even if experimenters begin with different probabilities concerning hypotheses $h_1, \ldots, h_n$ as long as these are non-zero and they agree on the likelihoods P($e_k|h_i$) of the outcomes e_k then, under very general conditions, repeated experimentation and conditionalization will result in the convergence of their degrees of belief concerning the h_i. However, this result is cold comfort since even approximate agreement may require an

unrealistically large amount of experimentation. Also, there is nothing in subjective Bayesianism that requires agreement on the likelihoods on which the convergence results depend.

Some Bayesians have suggested principles or considerations that constrain rational probability distributions. One way of doing this invokes 'principles of indifference'. The simplest indifference principle says that if one has no definite knowledge concerning a set of exclusive hypotheses, one ought to assign them equal probabilities. For example, if one had no knowledge concerning whether a ball to be drawn from an urn was red, *R*, or not red, $-R$, then one ought to assign the two hypotheses a probability of 0.5. The trouble with this proposal is that the principle of indifference is very sensitive to exactly how the hypotheses are described. If the problem were described in terms of the hypotheses *R*, *G* (the ball is green), and *B* (the ball is blue) then the principle of indifference entails probabilities of a third for each hypothesis. More sophisticated indifference principles have been proposed (Jaynes 1968) that give unambiguous probability assignments in certain situations. But the situations in which these principles apply are highly idealized and, in any case, it is not at all clear why the probabilities they assign are more rational than alternatives.

Another approach to constraining rational probability distributions appeals to logical probability. The idea is that considerations of logic determine conditional probabilities P($R|Q$); the degree to which *Q* probabilifies *R*. This proposal has been developed for simple formal languages. Carnap (1950) introduced a number of such measures (see Carnap, R. §5). For example, if a first-order language contains monadic predicates *F* and *G* and names $a, b, c, \dots$ then one measure assigns equal probability to each 'state description' $Fa \,\&\, Ga \,\&\, Fb \,\&\, Gb \,\&\, \dots$. One problem with this suggestion is that it precludes learning from experience since propositions concerning different individuals are probabilistically independent. A different suggestion assigns equal probability to each 'structure description' and then divides the probabilities equally among the state descriptions that satisfy the structure descriptions. The trouble with this idea is that it precludes assigning probabilities greater than 0 to generalizations. This can also be remedied (Hintikka 1966). However, no one has proposed a characterization of logical probability that is both applicable to ordinary beliefs and rationally compelling.

Another proposal for constraining rational probability distributions has received some discussion. It is that rational distributions are determined by consensus relative to a group (Lehrer and Wagner 1981). The idea is that a rational probability distribution relative to a group of 'experts' can be extracted by taking a weighted average - the weights representing group members' assessments of one another's reliabilities - of the degrees of belief of members of the group. This proposal has some awkward consequences. Specifically, all the members of the group can agree that two events are probabilistically independent, and yet the consensus distribution makes them dependent (Laddaga and Loewer 1985). The proposal is also too relativistic to represent rational priors. The problem of the priors is as unsolved today as it was when Bayes first proved his theorem.

Probability, interpretations of

The term 'probability' and its cognates occur frequently in both everyday and philosophical discourse. Unlike many other concepts, it is unprofitable to view 'probability' as having a unique meaning. Instead, there exist a number of distinct, albeit related, concepts, of which we here mention five: the classical or equiprobable view, the relative frequency view, the subjectivist or personalist view, the propensity view, and the logical probability view. None of these captures all of our legitimate uses of the term 'probability', which range from the clearly subjective, as in our assessment of the likelihood of one football team beating another, through the inferential, as when one set of sentences lends a degree of inductive support to another sentence, to the obviously objective, as in the physical chance of a radioactive atom decaying in the next minute. It is often said that what all these interpretations have in common is that they are all described by the same simple mathematical theory - 'the theory of probability' to be found in most elementary probability textbooks - and it has traditionally been the task of any interpretation to conform to that theory. But this saying does not hold up under closer examination, and it is better to consider each approach as dealing with a separate subject matter, the structure of which determines the structure of the appropriate calculus.

1 The project

The task of interpreting probability might be approached in three distinct ways. The first way is to see the project as one of providing an explicit definition of the term 'probability' or, more usually, of the predicate 'has a probability of value *p*'. The second is to provide operational content to this predicate; in other words, to provide a set of procedures by means of which various probability values can be measured or attributed. This second task may result only in the provision of sufficient conditions for attributing the predicate, and conversely a solution to the first task may be accomplished without the definition providing us with a way to measure probability values. At one time, when verificationism held sway, a failure to provide measurement criteria was considered fatal to a definition (see Logical positivism §4; Operationalism), but we should keep separate these two tasks. The third approach is to provide an implicit definition of the predicate 'has a probability of value *p*' by means of an axiomatized theory of probability, followed by an interpretation or model for that theory. That is, because the concept of probability is often considered to be mysterious and inaccessible to observation in a way that the concept of, say, blue, is not, the best and perhaps the only way of providing content to the concept is by constructing a detailed theory of probability and providing a model within which the theory is true. This third project consists in putting structural constraints on possible interpretations of a probability function, and it will not ordinarily result in an explicit definition. It will also not usually assign specific values to outcomes, except for certain extremal values, such as the certain or the impossible event.

2 The formal theory

The structure of elementary probability theory is often motivated by an appeal to familiar facts about relative frequencies. Suppose that a chance process, such as rolling a die, has *N* possible outcomes which form an outcome space $\Omega = \{1, 2, 3, 4, 5, 6\}$. By taking subsets of Ω, such as $\{2, 4, 6\}$, we have an event consisting in the die coming up even. Then take all possible subsets of Ωand this will form an algebra A of subsets of Ω, for example, a set of subsets of Ωclosed under complementation ('negation') and union ('disjunction'). Let us say that an event *E* in A occurs if the elementary outcome, such as '2', is in *E*. Then we can define a probability function P over A by letting $\mathrm{P}(E) =$ the number of times *E* occurs/the total number of repetitions of the chance process. This immediately gives us that

(1) $\mathrm{P}(\Omega) = 1$
(2) $\mathrm{P}(E) \geq 0$
(3) If two events *E* and *F* are mutually exclusive, then $\mathrm{P}(E \cup F) = \mathrm{P}(E) + \mathrm{P}(F)$.

For mathematical convenience, this elementary theory is usually extended by requiring countable additivity, wherein (3) is replaced by

(3′) $\mathrm{P}(\cup_{i=1}^{\infty} E_i) \sum_{i=1}^{\infty} \mathrm{P}(E_i)$ when the E_i are all mutually disjoint.

(The structure of A then needs to be more complex in ways that are inessential here.)

An important definition to add is that of conditional probability, $\mathrm{P}(A \mid B)$, the probability of *A* given *B*, defined as $\mathrm{P}(A \mid B) = \mathrm{P}(A \cap B)/\mathrm{P}(B)$. Two elements of A are *independent* if and only if $\mathrm{P}(A \mid B) = \mathrm{P}(A)$ or, equivalently, if $\mathrm{P}(A \cap B = \mathrm{P}(A) \times \mathrm{P}(B)$.

This abstract calculus is now no longer tied to the particular interpretation with which we began, and the algebra can be one of propositions rather than events, an ontology preferable for logical or subjective interpretations. Different accounts of probability can now be compared to this axiomatic theory.

3 Relative frequency theories

Here the ontology is one of event types, and the probability is explicitly defined either as the actual finite relative frequency as in §2 above, or as the limit value of the relative frequency when the total number of repetitions goes to infinity. This gives the value of the probability as an empirical property of the sequence or reference class of outcomes which generates the frequency, rather than absolutely. A naïve finite frequency interpretation is clearly unsatisfactory. Suppose a die is rolled a finite number of times *N*. Then no outcome, say a '6', can have a probability value more fine-grained than on a scale 0, $1/N$, $2/N$, …, l. Thus, after two throws, a '6' could only have a probability of 0, 0.5, or 1. This problem could be circumvented by requiring sufficiently many repetitions, where 'sufficiently many' would be a function of the number of possible outcomes and degree of precision required. A more standard remedy for this problem is to move to a limiting relative frequency interpretation, wherein the probability value is simply defined as the limit of m/N as $N \to \infty$, where *m* is the number of successes. This solves our first, definitional, task, but it produces a difficulty for the measurement project, for there is no guarantee that the value of the relative frequency after, say, 1,000 repetitions, will be the same as, or close to, the limiting value, because an unusual run of outcomes could occur initially. What one can do is appeal to the strong law of large numbers for binary valued outcomes, which asserts that if the repetitions of the experiment are independent and identically distributed (that is, the probability does not vary from repetition to repetition) then for every $\varepsilon > 0$, with probability one $\mid m/N - p \mid > \varepsilon$ only finitely often.

This provides assurance that in the long run, the probability that the limiting frequency will differ from the 'true' value of *p* is zero, but at the cost of introducing a second order probability which in turn needs to be interpreted. As an additional requirement, Richard von Mises (1957) correctly insisted that limiting frequency values can only be drawn from random sequences of data. Thus, if our die gave us the sequence of outcomes 1, 2, 3, 4, 5, 6, 1, 2, 3, 4, 5, 6, …, the limiting frequency of a '2' would be 1/6, but quite clearly on every $(6N+2)\mathrm{nd}$ throw ($N = 0, 1, 2, \ldots$) the probability of '2' would be 1, and would be 0 on any other throw. This highlights what is known as the problem of single-case probabilities - how do we transfer a probability value from a class to a single outcome? A standard answer is that the appropriate frequency for an outcome type is one drawn from a random sequence. Attempts to solve this single-case problem have led to complex and fascinating theories of randomness and statistical relevance, each of which is of philosophical interest in its own right (Sklar 1993).

4 Propensity theories

We have seen above that relative frequencies are defined relative to a class of outcomes. If we focus on the fact that outcomes can be produced by a fixed set of generating conditions, then it is reasonable to attribute probabilities to a system in a physical context, especially when the system producing the outcomes is irreducibly indeterministic. This gives us a chance disposition or *propensity* to produce a given outcome. For example, the probability of decay within the next minute is a physical property of a radioactive atom, just as is its atomic weight. This view, which seems to have originated with C.S. Peirce, and was resurrected by Karl Popper (see Popper, K.R. §3), has been criticized as excessively metaphysical. This is an unfair criticism, for the propensity value can be measured empirically for a system with a fixed propensity by employing the strong law of large numbers, mentioned above, together with statistical estimation techniques, thus satisfying the operational criterion. Being a thoroughly ontological interpretation, propensity accounts do not provide an explicit reductionist definition of probability, for propensities are basic, often primitive, properties of the world. However, no satisfactory solution has yet been given for the third project of providing a propensity calculus. Nor, despite a number of efforts by Popper and others, has a satisfactory argument been provided that quantum probabilities are

obviously propensities in any detailed sense (see Causation; Quantum mechanics, interpretation of; Statistics).

5 Subjective probabilities

In contrast to the objective interpretations just described, probability has always had a close relation with degrees of rational belief. Within this tradition, one can measure such degrees of belief operationally by means of betting behaviour. Here the elements to which the probabilities attribute values are propositions or sentences rather than events. By means of an ingenious operational process, known as the Dutch book method, within which the probability value is defined in terms of the lowest odds at which the gambler will accept a bet, one can show that plausible constraints on rational behaviour are satisfied if and only if axioms (1)-(3) and the definition of conditional probability of §2 hold. The subjective probability assignments are then said to be coherent. Thus we have satisfied the second and third criteria cited earlier, although it should be noted that different individuals can assign widely different values to a contingent proposition and both be coherent. De Finetti (1937), however, held that (3′) was not true for subjective probabilities because placing an infinite number of bets makes no sense for human agents. The Dutch book method will give us what are called prior probabilities but, except for extremal values, these are not arrived at by an a priori process. Rather, they are the expression of an unarticulated amalgamation of background knowledge. Although there is some controversy over how best to revise beliefs in the light of empirical evidence, the traditional way to do this is via conditionalization, using Bayes’ theorem. If H_j is a hypothesis (say that the die is fair), *E* is empirical evidence (say data from throws) and P_0 is our prior subjective probability assignment, then

$$\mathrm{P}_1(H_j) = \mathrm{P}_0(H_j \mid E) = \mathrm{P}_0(E \mid H_j)\mathrm{P}_0(H_j) / \sum_i \mathrm{P}_0(E \mid H_i)\mathrm{P}_0(H_i)$$

where $\{H_i\}$ is the set of hypotheses under consideration and P_1 is the new, posterior, probability assignment. Provided that the members of $\{H_i\}$ are distinct hypotheses (only one can be true at any time) and that $\sum_i \mathrm{P}_0(H_i) = 1$ (the possibility that no member of $\{H_i\}$ is true is not entertained), $\sum_i \mathrm{P}_0(E \mid H_i)\mathrm{P}_0(H_i) = \mathrm{P}_0(E)$, which gives $\mathrm{P}_1(H_j) = \mathrm{P}_0(H_j \mid E)\mathrm{P}_0(H_j)/\mathrm{P}_0(E)$.

The above gives us a normative theory of how agents should distribute their degrees of belief, but there has always been a divergence between this normative Bayesianism and individuals’ actual degrees of belief. Investigations by psychologists and economists have revealed systematic differences from Bayesian prescriptions, even by agents well-versed in probabilistic reasoning.

6 Classical interpretations of probability

This approach allocates probability values by dividing the outcomes into equipossible cases, and then using a principle of indifference to give each equipossible case an equal probability. Thus, if one considers, on the basis of symmetry, that each side of a die is just as likely to come up as any other side, then the classical theory attributes a value of $1{:}\,6$ to each such outcome. This is not, contrary to many claims, always an a priori attribution, because it generally depends upon some specific empirical knowledge about symmetries of the system. The classical approach is unsatisfactory for a variety of reasons. First, it is limited to situations in which equipossible cases are available. Second, there are straightforward paradoxes associated with this approach, which allow different probability values to be attached to the same event. The simplest is one introduced by Bertrand. Suppose you have wine and water mixed, in a ratio somewhere between one part of water to one of wine, and two parts water to one of wine. Using an indifference principle on the ratio water:wine, we have that the probability of the ratio lying between 1 and 1.5 is $1{:}\,2$. Now consider the ratio wine:water. This can lie between $1{:}\,2$ and 1, and the water:wine ratio of $1{:}\,5$ is a wine:water ratio of $2{:}\,3$. The indifference principle then says that the probability of this ratio lying between 1 and $2{:}\,3$ has a probability of $2{:}\,3$. This is contradictory.

7 Logical interpretations and other approaches

The logical approach takes propositions as the objects to which probabilities are ascribed, and interprets a conditional probability as a logical relation giving a degree of inductive support from the conditioning sentence to the conditioned. Thus, $\mathrm{P}(H \mid E)$ is the degree of inductive support that the evidence statement *E* gives to the hypothesis *H*. To measure $\mathrm{P}(H \mid E)$, Carnap (1945) considered state descriptions. In the simplest case, one lists all the individuals $a_1 \ldots a_n$ in a world and all the predicates $F_1 \ldots F_r$. Then a state description is an attribution of

F_i or $\sim F_i$ to each individual a_j for all *i* and *j*, that is, a maximally consistent description of some possible world. If we now attribute, in an a priori way, a measure *m* on state descriptions (and this can be done in a number of ways), then the conditional logical probability is just $m(H \mathbin{\&} E)/m(E)$. The principal drawback to using state descriptions is that learning from experience is impossible, simply because all predicates are logically independent and hence observing an instance of the property it represents gives no information about instances of any other. For this reason, Carnap switched to structure descriptions, within which individuals are indistinguishable. Interestingly, the differences between Maxwell-Boltzmann statistics, Bose-Einstein, and Fermi-Dirac statistics in physics are representable as differences that depend upon which states are physically possible. Because it is an empirical fact which particles satisfy which statistics, this sheds considerable doubt upon the whole enterprise of making a priori probability attributions.

There are now well-entrenched theories of comparative probability within which numerical values are not assigned, but one outcome is simply considered to be at least as probable as another. Alternatively, rather than assigning specific values to a proposition, intervals of probability can be assigned to mirror our uncertainty about the correct value via upper and lower probabilities. The connections between subjective probability and objective chance are now also the subject of much interest.

Process philosophy

In the broad sense, the term 'process philosophy' refers to all worldviews holding that process or becoming is more fundamental than unchanging being. For example, an anthology titled Philosophers of Process (1965) includes selections from Samuel Alexander, Henri Bergson, John Dewey, William James, Lloyd Morgan, Charles Peirce and Alfred North Whitehead, with an introduction by Charles Hartshorne. Some lists include Hegel and Heraclitus. The term has widely come to refer in particular, however, to the movement inaugurated by Whitehead and extended by Hartshorne. Here, process philosophy is treated in this narrower sense.

Philosophy's central task, process philosophers hold, is to develop a metaphysical cosmology that is self-consistent and adequate to all experienced facts. To be adequate, it cannot be based solely on the natural sciences, but must give equal weight to aesthetic, ethical and religious intuitions. Philosophy's chief importance, in fact, derives from its integration of science and religion into a rational scheme of thought. This integration is impossible, however, unless exaggerations on both sides are overcome. On the side of science, the main exaggerations involve 'scientific materialism' and the 'sensationalist' doctrine of perception. On the side of religion, the chief exaggeration has been the idea of divine omnipotence. Process philosophy replaces these ideas with a 'panexperientialist' ontology, a doctrine of perception in which nonsensory 'prehension' is fundamental, and a doctrine of divine power as persuasive rather than coercive.

1 Philosophy's central task

Process philosophy is based on the conviction that the central task of philosophy is to construct a cosmology in which all intuitions well-grounded in human experience can be reconciled. Whereas cosmologies were traditionally based on religious, ethical and aesthetic as well as scientific experiences, cosmology in the modern period has increasingly been based on science alone. Process philosophers find this modern cosmology, which can be called 'scientific materialism', inadequate to those human intuitions that are usually called aesthetic, ethical and religious and, more generally, to those 'commonsense' beliefs that we cannot help presupposing in practice - such as the belief that our thoughts and actions are not wholly determined by antecedent causes. Such beliefs, rather than being explained away, should provide the final criterion for philosophical thought. In enunciating this criterion, Whitehead (1929) and Hartshorne (1970) are adopting the pragmatic maxim of Peirce and James that, if an idea cannot be lived in practice, it should not be affirmed in theory. The worldview of scientific materialism is also held to be inadequate for science itself. Although this is most obvious in biology and psychology (see §3 below), it is true even for physics (Whitehead 1925).

Part and parcel of philosophy's task is its role as 'the critic of abstractions'. Because of the tendency for overstatement, the abstractions from the more specialized disciplines usually need to be reformulated before they can be integrated into a self-consistent cosmology (Whitehead 1925). Because the abstractions of the physical sciences have recently been dominant, the primary critical task now is 'to challenge the half-truths constituting the scientific first principles' (Whitehead [1929] 1978: 10). At the root of these half-truths is usually the 'fallacy of misplaced concreteness', in which an abstraction from something, useful for particular purposes, is identified with the concrete thing itself. This fallacy lies behind scientific materialism, according to which everything, including human experience, is to be explained in terms of the locomotion of bits of matter devoid of spontaneity, internal process and intrinsic value (Whitehead 1925). The suggested alternative is to reconceive the basic units of the world as processes (see Whitehead, A.N.).

2 Two kinds of process

Although 'process philosophy' (which Whitehead himself did not use) probably became the label for the school of thought he founded primarily because of the title of his main work, *Process and Reality* (1929), the term is apt: 'The reality is the process' and 'an actual entity is a process' (Whitehead [1925] 1967: 72; [1929] 1978: 41). Whereas all process philosophies in the broad sense could agree with these statements, it is the particular interpretation given to them that constitutes the distinctiveness of Whiteheadian process philosophy. Central to this distinctiveness is the twofold idea that the actual units comprising the universe are momentary 'occasions of experience' involving two kinds of process.

Partly through the influence of quantum physics, Whitehead conceived of the most fundamental units of the world, the most fully actual entities, not as enduring individuals but as momentary events. Enduring individuals, such as electrons, molecules, and minds, are 'temporally ordered societies' of these momentary events. The idea that actual entities are events with both spatial and temporal extensiveness is indicated by calling them 'actual occasions' (Whitehead [1929] 1978: 77). Their temporal extensiveness means that they cannot exist at an 'instant' (understood as a durationless slice of time). Rather, they constitute, as Bergson had suggested, a more or less brief duration (from perhaps less than a billionth of a second in subatomic events to perhaps a tenth of a second at the level of human experience).

This idea paves the way for recognizing two kinds of process: a process within an actual occasion, called 'concrescence' (because it involves moving from potentiality to concreteness), and a process between actual occasions, called 'transition'. These two kinds of process involve the two basic kinds of causation: 'efficient causation expresses the transition from actual entity to actual entity; and final causation expresses the internal process whereby the actual entity becomes itself'. Through this distinction Whitehead seeks to fulfil a central task of philosophy: 'to exhibit final and efficient causes in their proper relation to each other' ([1929] 1978: 150, 84). This proper relation is that every actual occasion begins by receiving efficient causation from prior actual occasions, completes itself by exercising final causation, understood as self-determination, and then exercises efficient causation upon following occasions. The temporal process involves a perpetual oscillation between efficient and final causation.

The two previous paragraphs provide two aspects of Whitehead's alternative to materialism's way of overcoming dualism in favour of a cosmology with only one type of actual entity. According to Cartesian dualism, minds were temporal but not spatial, while material bodies were spatially extended but essentially nontemporal (being able to exist at an instant). Whitehead's idea that all actual entities are spatiotemporal events overcomes that dualism. His idea that these events involve both concrescence and transition overcomes the further dualism between actual entities that can exert only efficient causation and those that can exercise self-determination. The central feature of Cartesianism, however, was the dualism between actual entities with experience and those without. This dualism is overcome through the rejection of 'vacuous actualities', meaning things that are fully actual and yet void of experience. This rejection is expressed positively by considering all actual occasions to be 'occasions of experience' (Whitehead [1929] 1978: 29, 167, 189). This doctrine means, with regard to the internal process of concrescence, that 'process is the becoming of experience' (Whitehead [1929] 1978: 166). The meaning is not that all actual entities are conscious - most are not - but that they have some degree of feeling.

Although 'panpsychism' is the customary name for philosophies of this sort, 'panexperientialism' is better for this particular version, partly because the term 'psyche', besides suggesting experience too sophisticated to attribute to atoms or even cells, also suggests that the ultimate units endure through time, rather than being momentary experiences. Another essential feature of process philosophy's version is that the 'pan', meaning 'all', does not refer to literally all things but only to all genuine individuals (see Panpsychism §1). This distinction is central to process philosophy's solution to the mind-body problem.

3 The mind-body problem

Panexperientialists, like materialists, consider insoluble the problem of dualistic interaction: How could mind and brain cells, understood as actualities of ontologically different types, interact? Materialism seeks to avoid this problem by thinking of the mind as somehow identical with the brain. However, besides still having the problem of how conscious experience could arise out of insentient neurons, materialism is also hard-pressed to explain the apparent unity and freedom of our experience. The move by eliminative materialists, denying that there is any experience, unity or freedom to explain, rejects in theory what is inevitably presupposed in practice. Whiteheadian process philosophy suggests, on the basis of its panexperientialism, a 'nondualistic interactionism' meant to avoid the problems of both dualism and materialism. With dualism, it distinguishes (numerically) between mind and brain. The distinct reality of the mind, as a temporally ordered society of very high-level occasions of experience, provides a locus for the unity of our experience and its power to exercise self-determination. But by rejecting dualism's assumption that the mind is ontologically different from the brain cells, panexperientialism removes the main obstacle to understanding how our experiences could interact with our brain cells. As Hartshorne puts it: 'cells can influence our human experiences because they have feelings that we can feel. To deal with the

influences of human experiences upon cells, one turns this around. *We* have feelings that *cells* can feel' (1962: 229).

The freedom of bodily action has also been a problem for materialists, who may admit that they cannot help presupposing this freedom while claiming that the scientific worldview has no room for it. One of the assumptions behind this claim is that the behaviour of subatomic particles is fully specified by the laws of physics. A second is that all wholes, including human beings, are analogous to rocks and billiard balls, so that all vertical causation must run upward, from the most elementary parts to the whole. In process philosophy's panexperientialist ontology, by contrast, all actual entities are internally constituted by their relations to other occasions. This view allows for the emergence of higher-level actual occasions, so that spatiotemporal societies of actual entities can be of two basic types: besides aggregational societies, such as rocks, there is what Hartshorne (1972) calls the 'compound individual', in which a society with the requisite complexity gives rise to a 'dominant' member, which can then exercise downward causation on the rest of the society. This downward causation is possible, furthermore, because the 'laws' of nature are really its most widespread habits, and because atoms and subatomic particles are open to the particular influences of the environment in which they find themselves (Whitehead [1938] 1966: 154-5;[1933] 1967: 41).

4 Perception and prehension

Another distinctive feature of Whiteheadian process philosophy is its challenge to the 'sensationalist' theory of perception, according to which all knowledge of the world beyond the mind comes through sensory perception (see Perception, epistemic issues in). More fundamental than sensory perception, suggests Whitehead (1925), is a nonsensory mode of perception, called 'prehension', which may or may not be conscious. One example (which we call 'memory') occurs when an occasion of experience directly perceives occasions in its own past. Another instance is the mind's direct reception of influences from its brain (which sensory perception presupposes). This direct prehension of other actualities, through which we know of the existence of the 'external world', is also called 'perception in the mode of causal efficacy', because it provides the experiential basis, denied by Hume, for our idea of causation as real influence.

This idea of nonsensory prehension is central to process philosophy. It is implicit in the idea of panexperientialism: because sensory perception can be attributed only to organisms with sensory organs, the idea that all actual entities have experience presupposes a more primitive mode of perceptual experience that can be generalized to all individuals whatsoever. This idea is also presupposed in the acceptance of aesthetic, ethical and religious experiences as genuine apprehensions. It is crucial, thereby, to the task through which philosophy 'attains its chief importance,' that of fusing science and religion 'into one rational scheme of thought' (Whitehead [1929] 1978: 15).

5 Reconciling science and religion

One side of this task of reconciling science and religion involves what has been discussed above - the replacement of the materialistic worldview, with which science has recently been associated, with panexperientialism, which allows religious and moral experience as well as freedom to be taken seriously. The other side of the task involves overcoming exaggerations from the religious side that conflict with necessary assumptions of science. Here the main exaggeration involves the idea of divine power. Whitehead and Hartshorne do believe that a metaphysical description of reality points to the necessity of a supreme agent to which the name 'God' can meaningfully be applied. (Arguments for the existence of God are developed much more fully by Hartshorne (1941, 1962) than by Whitehead.) But they strongly reject the traditional doctrine of divine power, according to which God, having created the world *ex nihilo*, can interrupt its basic causal processes - a doctrine that, besides creating an insuperable problem of evil, also conflicts with the assumption of scientific naturalism that no such interruptions can occur. Their alternative proposal is that the power of God is persuasive, not coercive (Whitehead 1929, 1933; Hartshorne 1984).

6 Developments in the movement

Although Whitehead was one of the first philosophers to be included in 'The Library of Living Philosophers' (Schilpp 1941), his philosophy was largely ignored in the decades subsequent to its articulation in the 1920s and

1930s, partly because of the turn to anti-metaphysical forms of philosophy. Another factor was that, even within circles still interested in developing a naturalistic cosmology, Whitehead's panexperientialism and affirmation of God were felt to exceed the limits of a proper naturalism, which was largely equated with materialism (see Materialism). The most prominent advocate of Whiteheadian process philosophy in the following decades, furthermore, was Hartshorne, whose focus on the idea of God, while creating interest in theological faculties, reinforced suspicions in philosophical circles. Around 1960, however, a spate of books on Whitehead's philosophy inaugurated a period of greater interest (Lawrence 1956; Leclerc 1958, 1961; Christian 1959; Lowe 1962; Sherburne 1961; Kline 1963). In 1971, a journal, *Process Studies*, was created for the purpose of furthering the study and development of process thinking. In 1991, a volume devoted to the philosophy of Hartshorne appeared in the 'Library of Living Philosophers' (Hahn 1991).

Whiteheadian process philosophy has exerted some influence in a number of branches of philosophy, such as the philosophies of science, education, and art. Its major influence thus far, however, has continued to be in the philosophy of religion (Cobb 1965, 1969; Frankenberry 1987; Griffin 1976, 1991; Ogden 1966), including discussions of the relation between science and religion in particular (Barbour 1966, 1990).

Process theism

Process theism is a twentieth-century school of theological thought that offers a nonclassical understanding of the relationship between God and the world. Classical Christian theists maintain that God created the world out of nothing and that God not only can, but does, unilaterally intervene in earthly affairs. Process theists, in contrast, maintain that God and the basic material out of which the rest of reality is composed are coeternal. Moreover, process theists believe that all actual entities always possess some degree of self-determination. God, it is held, does present to every actual entity at every moment the best available course of action. And each entity does feel some compulsion to act in accordance with this divine lure. But process theists deny that God possesses the capacity to control unilaterally the activity of any entity. Thus, what occurs in relation to every aspect of reality involving a multiplicity of entities - for example, what happens in relation to every earthly state of affairs - is always a cooperative effort.

This understanding of the God-world relationship has significant theological implications. For instance, while classical Christians must attempt to explain why God does not unilaterally intervene more frequently to prevent horrific evils, process theists face no such challenge since the God of process thought cannot unilaterally control any earthly state of affairs. On the other hand, while most classical Christians maintain that God at times unilaterally intervenes in our world primarily because divine assistance has been requested, process theists naturally deny that God can be petitioned efficaciously in this sense since they believe that God is already influencing all aspects of reality to the greatest possible extent. Moreover, while most Christian theists believe that God will at some point in time unilaterally bring our current form of existence to an end, process theists maintain that the same co-creative process now in place will continue indefinitely.

Not everyone finds the process characterization of the God-world relationship convincing or appealing. But few deny that process theism has become a significant force in modern American theology.

1 Basic metaphysical tenets

The basic metaphysical roots of process theism are found in the work of Alfred North Whitehead (§4), with much of its explicit theological framework the result of the interpretation of Whitehead offered by Charles Hartshorne. While process theists differ among themselves on some issues, there is widespread agreement concerning the basic nature of reality.

Within the process metaphysic, the most fundamental constituents of reality are not ‘things’ or enduring substances. Rather, they are units of experience - usually called actual entities - that momentarily come into existence and then immediately perish. Each of these actual entities has a physical and mental component. As the entity comes into existence, the physical component takes account of (prehends) two things: its past - all that has gone before it; and God’s initial aim - that which God sees as the best possibility open to it, given the concrete situation. The entity also automatically feels some impulse to act in accordance with God’s initial aim. However, each actual entity has at least some power of self-determination, the function of its mental component. Thus, no actual entity is ever forced to do what God wants. It always has the power to choose its own subjective aim from among God’s initial aim and all the real possibilities its past has made available. Once its decision is made, once the entity has unified the data from its perspective, it perishes as an experiencing subject and remains only as part of the past for all subsequent actual entities.

Some sets of actual entities, however, have a unity of their own. In these societies of entities, each entity still inherits its past from all other entities. But the inheritance from the past members of its own society is dominant. A subatomic particle such as an electron is a good example of a basic entity of this sort. There is no enduring substance that can be identified as an electron. But there are societies of ‘electronic entities’ in which each largely repeats the form of the previous entity in its society. In fact, the carry-over is so great that any given society of electrons appears to behave as if it were a single entity. Accordingly, basic societies or aggregates such as these are often called ‘enduring individuals’.

Moreover, basic enduring individuals of a given type normally combine into more complex enduring individuals. Societies of subatomic particles form enduring atomic individuals, which themselves combine with other enduring

atomic individuals to form enduring molecular individuals, which in turn combine with other molecular individuals. In the higher-order animal realm, for example, various societies of enduring cellular individuals combine to form enduring multicellular animal bodies with a central nervous system. In some of these enduring individuals, the enduring nervous system gives rise to what we label the enduring human mind or soul.

In short, in process thought the whole is truly greater than the sum of its parts. What we perceive phenomenally as enduring individuals - for example, humans, dogs, cats and trees - are not just bits of inanimate and animate matter in a certain configuration. Such enduring individuals are really 'societies of societies' of varying complexity - with some possessing a unity of experience (humans, dogs, cats) and others not (rocks, stars, books). Moreover, each society possessing a unity of experience retains to some extent its own autonomous power of self-determination even as it combines with other societies to create more complex societies (enduring individuals). The more complex an enduring individual of this type, the greater the influence of its mental pole, that is, the more actual options it has open to it and the more conscious it is of such options. This explains why humans behave in much more creative ways than dogs, which in turn behave in much more innovative ways than plants.

Within process thought, God is not an exception to this metaphysical order. But while there is disagreement over whether God is an enduring individual or an actual entity, God clearly occupies a unique position in the process system. Only God takes account of (prehends) all that happens in the world. God alone experiences all that every entity experiences. Thus, although each actual entity exists only momentarily, its past is not lost. All that has occurred exists everlastingly as a unified whole in God's consciousness. It is in this sense that the whole universe is included in, and penetrated by, God - that the world is God's body (see God, concepts of §8).

God, however, also responds to what is experienced. God, in this capacity, is aware of all harmonized possibilities open to the world. It is on the basis of this knowledge that God continuously presents to every entity at every moment the optimum real possibilities open to it. Thus, while God is not an exception to the metaphysical rules which govern the process system, God is certainly the most significant individual within this system. God not only exerts more influence on the direction of the process than does any other enduring individual, God alone unifies this ontological process into a harmonized whole.

2 Comparison with classical Christian theism

Process theism is frequently compared to classical Christian theism by proponents and critics alike. Moreover, the two systems are in some ways similar. Proponents of both argue, in opposition to atheism or pure pantheism, for the existence of a God who is in some sense ontologically distinct from the rest of reality. Both believe that only a being who is morally perfect is worthy of worship. However, the differences between process theism and classical Christian theism are many and significant. The most crucial concerns God's power. Classical Christians have always held that God has the capacity to control everything (see Omnipotence §1). They differ significantly on the extent to which God actually exercises this power. In fact, some classical Christians believe God seldom chooses to intervene unilaterally. But even these theists - often called free-will theists - still uniformly agree that God *could* unilaterally control all aspects of reality. The fact that God often chooses not to do so is considered a self-imposed limitation.

However, within the process system the situation is quite different. Since all actual entities always possess some degree of self-determination, God could not unilaterally control any aspect of reality involving other entities, even if God so desired. In other words, within process thought, the fact that God never imposes the divine will on other entities is not a self-limitation. Rather, it is a metaphysical reality to which even God is subject. Persuasive power, as opposed to coercive power, is all that is available to God.

Another important difference surfaces in relation to the origin of our world. Classical Christian theists have normally held that the world is totally dependent on God in the sense that it was created *ex nihilo*. Although they differ considerably on the exact manner in which they believe this was accomplished, they maintain that there was once a time (logically speaking) when only God existed and that all else has been created, directly or indirectly, by divine decree (see Creation and conservation, religious doctrine of).

Process theists, of course, do not agree. Since they believe that God cannot unilaterally control the activity of any other entity and that there has always existed a plurality of actual creative entities, they maintain that reality has always been the result of co-creative, interdependent activity. It is probably true, most process theists admit, that

there was once a time when all actual entities other than God existed in a state of random, nonpurposeful activity. Moreover, the fact that we now have a vast array of highly complex, multistructured societies of actual entities is viewed as a tribute to the effectiveness of God's persuasive power. But God alone can guarantee nothing. God has always been dependent on the cooperation of all other self-determining entities to accomplish any creative goal.

Another fundamental classical Christian belief is that the world will reach a final and fixed state, a final *eschaton*. But process theists deny that there will ever be a time when the current process will stop. They deny, for example, that there can be a fixed state in which individuals experience eternal bliss or torment (see Eschatology §1; Feminist theology §2). The universe might at some point in time arrive at a state in which all actual entities are experiencing the maximum degree of harmonious, intense novelty, the highest good from the process perspective. But there could be no assurance that such a state would be long-lasting. A period of triviality or discord, the greatest evils, could quickly follow. What does in fact occur will always depend on the manner in which all other actual entities respond to God's influence.

Finally, many classical Christians have thought it important to maintain that God is omniscient in the sense that all that has occurred or will occur, including all that we will freely choose to do in the future, is open to the divine vision (see Omniscience). But process theists, not surprisingly, deny that God possesses such insight. God does know all that has occurred. However, since all reality is interdependent in the sense that what exists at every moment includes the self-determination of entities other than God, infallible knowledge of the future is impossible for any being, including God.

3 Comparison with classical Christian theism (cont.)

The significance of these doctrinal differences becomes most apparent when considered in relation to Christian practice.

Petitionary prayer. Both classical Christians and process theists acknowledge the importance and efficacy of prayer in which God is asked to respond to concerns. Those in both camps agree, for instance, that prayer of this type can affect the petitioner as well as any others who are aware of prayers being offered on their behalf. Some in both camps even believe that those who do not know that prayers are being offered for them may experience some direct effect (see Prayer).

But for classical Christians the primary value of petitionary prayer lies in the fact that it sometimes initiates unilateral divine activity that would not occur if such activity were not freely requested. That is, such prayer is deemed important primarily because it is believed that certain states of affairs that God can and would like to bring about will occur only if divine assistance is sought. However, process theists naturally deny that petitionary prayer can ever be efficacious in this sense. Since process theists believe that all entities possess some power of self-determination, they naturally deny that a request for assistance can ever initiate *unilateral* intervention in earthly affairs. And since God is already doing all that is possible to persuade each entity at each moment to make the optimum choice, it can never be claimed that any activity on our part could induce God to become more involved than would otherwise have been the case.

Divine guidance. While it is important to note that both classical Christians and process theists share their thoughts and concerns with God in prayer, it is equally important to note that those in both camps also want God's perspective shared with them. That is, both classical Christians and process theists want to know God's will. Moreover, those in both camps believe that God not only can, but does, share the divine will with us (see Providence).

However, classical Christians differ significantly from process theists on the question of how such knowledge is attained. While classical Christians believe that the divine perspective is something that God always desires to share with us, they hold that God at times does so only if such guidance is requested (only if it is consciously sought). On the other hand, process theists, as we have seen, believe that God always automatically presents to each of us at every moment the best available option. Furthermore, while most classical Christians believe that we can, at times, come to a fairly clear, *conscious* understanding of what God believes or how God would have us act if we are open to God and diligent in our search, process theists disagree. They believe that the manner in which the divine will is shared with all entities makes clear, conscious knowledge of that which God would have us do a very rare phenomenon.

Evil. All theists continue to face the following challenge: if God is omnipotent and perfectly good, why is there so much seemingly unnecessary pain and suffering in our world? Since classical Christians believe that God can unilaterally intervene in earthly affairs, they must maintain that God has decided to allow each instance of evil because such evil is either a necessary antecedent causal condition for the actualization of some creative goal (for example, God's desire that we learn patience) or an unavoidable by-product of some creative goal (for example, God's desire that we exercise freedom of choice). In short, classical Christians must maintain that God is powerful enough to rid the world of all evil, but possesses morally sufficient reasons for not doing so (see Evil, problem of).

Process theists, however, find this line of reasoning totally implausible. As they see it, a perfectly good being who could do more to rid the world of evil would surely do so. But the God of process theism, they are quick to point out, is not faced with this choice. God does deplore evil and is always attempting to persuade all other entities to help actualize the best possible states of affairs. For instance, God was horrified by the Holocaust and tried in every way possible to influence those responsible not to commit such atrocities. But since God cannot unilaterally control the self-determining activity of any other entity, God is never in a position to prevent any instance of evil such activity might produce. And therefore the fact that evil states of affairs arise (and sometimes even proliferate) does not count against God's goodness.

4 Critical discussion

Critics of process thought fall into three major categories. Some reject it because they believe its theological system to be incompatible with classical Christian doctrine. Pinnock (1987) has argued, for instance, that process theism must be rejected because process theists do not acknowledge the total transcendence of God, the full divinity of Jesus or the supernatural origin of Scripture. However, while this type of criticism may serve a useful function within the classical Christian system itself - namely, to dissuade those who may initially find the process system appealing - its value in the general debate over the adequacy of process thought is questionable. Critical contentions of this sort do make it clear that classical Christians differ from process theists on important points; but the reality of such differences is something process theists readily acknowledge.

Other critics argue that process theism must be rejected because some of its basic contentions are false or implausible. For example, Gruenler (1983) argues that the basic process metaphysic is incompatible with modern relativity theory. Others find the process explication of how the world as we know it came to be quite implausible. An even more common criticism of this type, though, is the contention by classical Christian theists that a being with the acknowledged limitations in power of the God of process theism is too weak to be considered worthy of worship.

In response to this latter claim, process theists maintain (as noted before) that a God who is worthy of worship must be perfectly good, but argue that only the God of process theism meets this requirement. The powerful, independent God of classical Christian theism, they grant, might be viewed as a convenient wish-fulfiller. But such a being cannot justifiably be viewed as a caring friend worthy of our loving respect. Moreover, they continue, given the amount of unnecessary evil in our world, only a God who could not do more to remove it can be considered morally praiseworthy (see Goodness, perfect).

Finally, some critics challenge the internal consistency of the process system. One of the most significant of these challenges centres around the question of whether the God of process theism would coerce (unilaterally control) other entities if this were possible (Basinger 1988). If process theists decide that God would do so, it then becomes difficult to see how they can justifiably maintain (as many do) that coercion is morally incompatible with divine perfection (as Ford 1978 says), or that persuasion is the greatest of all powers, the only power capable of worthwhile results (as Cobb 1976 says). On the other hand, if process theists maintain that God would not coerce even if possible, it then becomes difficult to understand how process theists can justifiably criticize the God of classical free-will theism for not coercing more often. Process theists, the critics in question allege, cannot have it both ways. In response, some process theists (for example, Griffin 1991) acknowledge that the God of process theism would coerce if possible, but deny that this is inconsistent with continuing to maintain that persuasive power, if properly understood, is morally superior to coercive power.

It is, of course, too early to assess the lasting impact of process thought. But this unique metaphysical system is clearly a significant force in American theology, and there is little reason to believe that it will not continue to

offer an important alternative to classical Christian theism for some time to come.

Processes

A process is a course of change with a direction and internal order, where one stage leads on to the next. Processes can be physical (such as atomic decay), biological (such as the growth of living things), artificial (such as building a house) and social (such as carrying out a criminal investigation). Much of what is said about processes can be said about sequences of events. The concept of event, however, suggests a separate occurrence, whereas that of a process suggests something which is ongoing. There are matters, such as development in organisms, where to see what is happening as part of a process has an advantage over thinking of it as an event. Causes are generally spoken of as events, but the more dynamic concept of causal processes may get nearer to expressing the transition between cause and effect. Moreover, to explain something as a stage in a process can take account not only of what has happened in the past, but of what might happen in the future. This may (but need not) involve purpose; with organisms it involves development through functionally interrelated activities. In some social processes there can be a practical, moral significance in seeing a situation as a stage in a process, since this can encourage us to look to a further stage where something constructive might be brought out of what could otherwise be seen as simply an untoward event or an unhappy situation.

1 General nature and types of processes

Processes are systematic courses of change with an internal order and temporal direction. Their temporal direction consists in there being an absolute order in the stages by which they proceed. This need not imply that there is an absolute time apart from processes or events, and these might appear in a different order to observers in different frames of reference. But the order in which the stages of a process occur is irreversible. Most processes go towards completion at an end point, but this need not be so in all cases. There are also steady-state processes, periodic processes and staccato processes where the ongoing feature is one of sustaining a pattern.

A process has temporal parts. This is sometimes expressed by saying it ‘perdures’ - that is, it is not wholly present at any time. Substances which are wholly present at every time of their existence are said to ‘endure’. Processes mostly involve physical movement. Some, however, have an internal order not reducible to the direction of any movements that may accompany them. For instance, an intellectual process of argument proceeds through the participants seeing that one statement follows from another, or that it should be abandoned because of critical considerations raised in the course of the argument. An argument need not reach a conclusion - it can be broken off and resumed.

While all processes have an internal order and a direction, there are different kinds which, besides intellectual processes, include natural, artificial and social ones. Natural processes follow laws, as with the chemical reactions which are involved in the metabolism of food. Biological natural processes are clearly irreversible - digested food cannot be turned back into parts of plants and animals. However, some physical processes are said to be reversible, as when a rotating wheel is ‘put into reverse’. But here another process is set going whose stages run in the opposite direction, towards a state which is not identical to the originator of the process but is another of the same type.

Artificial processes are carried out teleologically by agents acting in natural conditions set by the available materials and the environment. Within these limits, the agents can sometimes vary the order in which what they do becomes a stage in a process. For instance, in constructing a house the foundations must be laid first and normally the walls built before the roof is put on. But the roof can be put on before the walls are built provided that there is a sufficient structure to support it. Natural processes can be interfered with through artificial processes, as in conducting experiments. The constituents of social processes are persons acting according to rules and conventions in environments set by natural and artificial processes. The upholding and administration of the Law is a collection of social processes with rules and conventions prescribing proper procedures (note that ‘process’ and ‘procedure’ have the same root). A legal trial is a social process - indeed ‘process’ is a technical term for legal proceedings.

Rules prescribe how certain social processes ought to be carried out. Customs and conventions show how a number of social processes are motivated by expectations as to how people are likely to behave according to the ways in which they have been socialized. The formal processes of law and government operate in a social

environment sustained by these informal processes. Generalizations about social processes (and also some natural ones) are often statistical (see Social laws).

2 Causation in processes

Artificial and social processes involve teleological causation where agents act purposively, but depend on efficient causation for the results of their actions (see Teleology). Natural processes in accordance with laws are not thought to involve teleology, though this is controversial in the case of some biological processes. In considering these, there is a distinction between causation which is internal to the process and that which consists of action on it from outside. W.E. Johnson (1934) used the term ‘immanent causation’ for the systematic changes due to co-variable and coordinated functioning in the process taken as a whole, and ‘transeunt causation’ for the action of separate elements on one another. Science aims to discover efficient causation between the elements of a system (for instance, the chemical actions in the process of metabolism). But the concept of immanent causation may still be needed for describing its functioning as a whole. The nourishing of the body is carried out through a great number of mutually supporting processes - the beating of the heart circulates the blood, and the heart will fail to beat unless the blood supply reaches it. There are also feed-back processes which come into effect to restore imbalances (for instance in keeping the body temperature within limits). These have been given the name ‘homeostasis’. They may not be teleological in the purposive sense, but are instances of immanent causation. Coordinated functioning in a changing system is the general character of what are called ‘organic processes’, as shown in the self-maintenance and development of living things.

3 Processes and events

Much of what is said philosophically about processes can also be said about events - for example, they have an internal order or direction, and an absolute order of before or after in their parts. What is pertinent here is how processes differ, if they do, from sequences of events. An event is an occurrence taken as a unit. It can be divided into temporal parts, each of which can then be taken as a shorter event. So the great storm in Britain in October 1989 can be taken as an event. It can be said that it was more severe at some times than at others, distinguishing its temporal parts as sub-events, such as the blowing of the gale from 1 a.m. to 1.15 a.m. It can then be said that the blowing of the gale at 1.10 a.m. caused the collapse of Mr Jones’ chimney (another event). Causation is often said to be a relation between events. It can also be spoken of in terms of processes: as the gale went on blowing even more fiercely, it caused the waves to go on rising higher and to flood the sea front. The event-form gives a sequence of occurrences; the process-form suggests something was going on. In this respect, to speak in terms of causal processes may come nearer to a dynamic description of what was happening.

Events are often expressed by participles forming gerunds (sometimes called verb nominalizations), which are parts of verbs construed as nouns and prefaced by ‘the’ or ‘a’. In the case of processes, the participle keeps its full verbal voice, perhaps in a continuous present. So in the phrase ‘the striking of the clock woke me up’, ‘the striking of the clock’ refers to an event, whereas in the phrase ‘I woke up while the clock was striking’, ‘while the clock was striking’ refers to a process.

4 Some metaphysical views

Some metaphysical views see reality as essentially in process - becoming, changing, passing away - or even claim that processes are all that exists. In that case there might be a philosophical description of the world expressed through verbs and adverbs. There would then be no things or persons, and this may raise a problem concerning agency. The subject of a proposition could be a dummy ‘it’; ‘Socrates is wise’ would become ‘It Socratizes wisely’ or ‘Socratizing wisely is going on’. Among the metaphysical religions, Buddhism has come nearest to such a view: in Buddhism there are no agents or substances, and the self is a stream of passing states. These are linked, however, in a causal process, or Karma (see Buddhist philosophy in India §1; Causation, Indian theories of).

A world of pure processes seems to need some structuring principle. The father of Western philosophies of process was Heraclitus. His philosophy has come to us in cryptic sayings, notably that ‘all things flow’ (*panta rei*). Yet this flux contains a principle, the Logos, which structures the flux by tensions of opposing forces, never coming to rest in a stable equilibrium. The contrasting position was taken by Parmenides, who so pressed the assertions that what is, is, and what is not, is not, as to deny the reality of change. This aroused serious discussion through the

arguments produced by Zeno of Elea. If everything not only is what it is, but is where it is, how does a moving body such as an arrow get from one position to another?

The problem of whether motion is a process of transition and not only occupancy of a succession of positions appears in a modern form in the so-called 'at-at' view given by Bertrand Russell. Motion is defined as *merely* (his italics) 'the occupation of different places at different times, subject to continuity' (1903: 473). Continuity here is density, and if space and time are dense continua this means that between any two positions or instants there will always be another. The 'at-at' view of motion states that a moving body will always be at the position appropriate to each instant. This, however, may not adequately meet Zeno's problem, which concerns motion as transition from one position to another. There is an analogous problem with the concept of change, defined as something having different properties at different times. This is perfectly true, but it loses the connotation of *changing* as being undergone by a subject.

The metaphysics of Aristotle contains a view of processes of becoming put in terms of the distinction between potentiality and actuality: things develop their potentiality towards full realization of their natures. This view of things as processes of becoming is circumscribed by his conception of a teleological development towards fixed essential natures. In spite of this limitation, Aristotle produced a subtle analytic treatment of the idea of a process of change. The word for this was *kinēsis*, as distinct from *metabolé* which was his general word for change. Our word 'kinetic' suggests movement, and *kinēsis* is best translated as 'process of change'. *Kinēsis* always contains a direction, a 'whence-whither' (*pothen poi*), but this need not be the direction of a movement in space; it can be the transition from one stage to another of a process of development. As a process of change *kinēsis* is continuous, though it may be broken off or interrupted.

Among other great philosophers, Hegel had a metaphysical system in which process played a central part (see Hegel, G.W.F. §4). Notably, world history was said to develop in a dialectical pattern analogous to a process of thought, where each stage expressed a partial aspect of an ultimate idea of fully conscious rationality. Marx re-interpreted the dialectical process not as a movement towards rationality, but as a movement of social change, where oppositions and tensions arise through conflicts between classes, at particular stages of technological development. The end state is conceived not as ideal rationality, but as a form of society in which classes, and thereby the conflicts which had driven the dialectical process, would be abolished (see Dialectical materialism). Views such as these have been castigated by Karl Popper (1957) as 'historicism', meaning by this that they impose a pattern on history. Nevertheless, such views have been constructive in encouraging the study of history as a complex of processes arising not only between individuals but out of relations between social institutions.

A philosophy of process which had a considerable influence in literature, for instance on Proust, was that of Bergson (see Bergson, H.-L. §4). Bergson saw reality as an open-ended evolutionary process, 'creative', as producing new forms of life. The word 'life' is in place here, because Bergson thought of evolution as driven by a living force, *élan vital*. Biological evolution is an integral part of this, in which we ourselves are participants. It is a temporal process in a strong sense - indeed Bergson spoke of reality as *durée*, real duration, continually creative of what is new. This is contrasted with time as measured by intellectual devices which represent a moving and changing reality as if it were a succession of states arrested at successive instants. Bergson held that the intellect was committed to this 'cinematographical' approach, and therefore failed to capture the moving and changing reality. There is, however, another mental capacity - 'intuition', through which we have an immediate experience of this reality in our own consciousness.

The later philosophy of Whitehead gives a metaphysics of a pluralistic universe, whose constituents are 'processes of becoming' (see Whitehead, A.N. §4). These are structured unities developing through their interrelations with each other. He used the generalized concept 'organism' for these unities. Their processes of becoming display reiterated patterns which can be given abstract formulations, especially through mathematics. Such intellectual formulations need not be considered distortions - Whitehead held that the world has a permanent basic structure which underlies them.

Whitehead's later philosophy is obscure, and it must be acknowledged that none of these metaphysical views, with the exception of that of Aristotle within his own terms, gives a precise critical discussion of what it is to be a process. Yet a number of matters such as growth, development, learning and producing creative work, are naturally thought of as processes, where understanding of what goes on at one stage is furthered by having regard to future

as well as to past stages.

Whitehead, A.N. (1929) *Process and Reality*, ed. D.R. Griffiths and D.W. Shelbourne, New York: Free Press; London: Collier Macmillan, 1978.(Outlines the metaphysics of processes of becoming referred to in §4 above. Other important works by Whitehead include *Science and the Modern World* (1926), *Adventures of Ideas* (1933) and *Modes of Thought* (1938), all published by Cambridge University Press.)

Proclus (*c.* AD 411-85)

The Greek Neoplatonist Proclus aimed to find a logical and metaphysical structure in which unity embraces but does not stifle diversity. He assumed the underlying unity of reality and of self, but was anxious to maintain the diversity of thought and existence. This led him to conceive of things as different species of one general whole, each part comprehending the rest but in its own specific, limited way. There are successive levels of awareness, thought and existence, ranging from that of ordinary experience, where we continuously have a passing understanding of the equally fleeting world, to that of ultimate unity, where we see the first principles and the total whole unqualified, as if by super-intuition. Reason, aided by imagination, and exercised by philosophy and science, elevates us towards that supreme state, which is at once the foundation of religious and of ethical values.

Proclus was interested in an integrated account of the nature of things. Asking questions about how and what we know, our perceptions and beliefs, prompts questions of the sort: what is the origin of knowledge? What is the nature of mind? Of the things we think and perceive? Of existence? For Proclus even questions about virtue, moral judgment and action, God, faith and salvation are all clarified by referring them to questions about their origins and nature. No subject escaped his attention, including the interpretation of poetic works by literary figures such as Homer, where Proclus saw language as a mediator to deeper truths. Philosophical inquiry leads to asking what order of reality substantiates things, whether in the field of mind, values, science or literature.

Proclus' system is complex, and he uses highly technical terms (most of which have their roots in Plato, Aristotle and Plotinus). But for him this is only appropriate to the richness of our conceptual world. We have complex and varied concepts about our surroundings and selves, not because humans necessarily have flamboyant fancies but because reality itself is complex. That we have glimpses of knowledge means that there is some unity between our mind and the objects of thought. Moreover, unity is essential to the identity of things, and without it they would be unintelligible, and conceptually unreal. The 'One' is a primitive absolute, and is fundamental to intelligibility and existence. Thinker, thoughts and realities are in some way one. Things are not disconnected but share layers of ever-increasing unity. Consequently questions about different kinds of being, knowledge, good, and so on, become questions about degrees.

Studying all this was not just a cerebral affair. To the Neoplatonist, understanding the scheme of things provided a guide on leading a good life and achieving what since Plato's days had been praised as the goal of human endeavour, 'true happiness' or eudaimonia*.*

1 Life

In his fifty-year career Proclus became the chief exponent of systematic Neoplatonism, the dominant philosophy of late antiquity. He was born in Byzantium, the capital of the eastern Roman Empire, but grew up in Lycia. The son of a successful advocate at the imperial court, he initially went to study law at Alexandria. However, while on a visit to Byzantium (associated with the foundation of a new university) he underwent a conversion to philosophy, which eventually led him to Athens at the age of nineteen. There Plutarch of Athens and Syrianus taught him Aristotle and Plato according to the Neoplatonic curriculum. He quickly rose to become the head of the prestigious Athenian School at the young age of twenty-five, until his death aged around seventy-five.

Proclus sought to practise what he taught. Biographical sketches and his poems reveal a man of passion. This he channelled into his academic work (teaching, seminars, writing), religious devotion and rigorous lifestyle (he was a vegetarian and abstemious). Friends, students and staff benefited regularly from his love and generosity, which compensated for his famous short temper and perfectionism. He was an inspiring figure and exercised his considerable authority politically both in and outside Athens. A proud defender of the 'Hellenic' values and religious multiformity, Proclus lived when Christianity became the state orthodoxy.

He was a prolific author, and we have evidence that he wrote more than forty titles. In keeping with the practice in the imperial Roman period, many of Proclus' treatises are extensive commentaries on classical greats. This does not mean they are not original: novel ideas and modifications or rejections of classical doctrines can be found in these commentaries, and in content there is little to distinguish them from monographs. For his general system the

main sources are the *Commentary on Plato's Parmenides*, *Platonic Theology* (synonymous with metaphysics), the study manual *Elements of Theology*, and for additional detail, the *Commentary on Plato's Timaeus*.

2 Metaphysics

Proclus' overall metaphysical standpoint he shares with his fellow Neoplatonists. He subscribes to realism, in that he accepts a reality independent of what we individuals think about it. But proper reality is not physical, because what we grasp with the five senses is episodic and often illusory. The things that exist are of the intellect - with the provision that such intellect and its ideas are not just personal but objective and universal (this can be traced to the revision of Aristotelian *nous* by the influential Alexander of Aphrodisias (§2)).

In his response to the problem of unity/diversity Proclus wants to steer between conceiving things as disparate and lumping them into an undifferentiated heap. He employs a rule of mixture that originally belonged to the theory of material stuffs in Anaxagoras (§3), but which near Plotinus' time had been extended to the domain of intellect and concepts: 'Everything is in everything, in a manner proper to each.' If things (conceptual and material) are ultimately one, they cannot have sharp boundaries to distinguish them, but must extend in some way 'all within all'. Similarity (and dissimilarity) supersede strict identity and difference (*Platonic Theology* III 7 S and W, VI 347-50 Portus; *Elements of Theology* proposition 108).

This metaphysical reason combines with the exhaustion of possible logical options under a heading *x* (that is to say, *x*; *x* and not-*x*; not-*x*) to yield the chains of 'intermediaries' for which Proclus is well known. Any two polar (directly opposite) terms have one or more intermediary, which is more or less similar to either pole. Although threefold leitmotifs are pre-eminent (for examples see below on participation), in fact as many intermediaries can be inserted as required (see Many-valued logics). However Proclus does not accept that everything we can think merits a niche in reality: only those that do not depend on a particular mind (*Commentary on Plato's Parmenides* col. 1054, 895-7) but can already stand on their own 'foundation' (*hypostasis*) (henceforth, some of these 'hypostatic' terms are indicated by capitalization). The task of the philosopher is to discover the true ones.

To make sense of diversity we group things with a common characteristic. But this raises the questions what is the status of such characteristic and what is its relation to the group and parts? Proclus distinguishes three senses of 'whole', and recognizes the full implication of saying that a whole is the sum of parts plus the cause of its unity (see also Aristotle, *Metaphysics* 1041b, and, especially, Plato, *Theaetetus* 204-5). The essential whole is a 'monad', a singularity that cannot be analysed: it is a 'whole prior to the parts' (*Elements of Theology* propositions 67-9). The characteristic group-type in its pure state is such an unanalysed whole. It stands as a prototype that qualifies and embraces all possible specific forms of it. The many parts of the whole express the prototype but unequally, because they have it in different conditions (for example, light itself, the light of the sun, firelight, glow-worm light). An attribute can thus be regarded as a family, a series, headed by its own prototype (for example, the monad of life), followed by the multitude of diverse forms where the attribute is found (for example, life of animal, life of plant).

In Platonic philosophy the relation of a 'Form' to its material particulars was often described as 'participation', a sharing-in, because each particular cannot be said to possess the entire Form. For the late Neoplatonist, participation extends to relations between conceptual entities also, so Proclus talks in general of what is 'participated in' and its 'participant'. Participation created many problems, not least, how can the Form be shared out and still maintain its integrity? By the whole-part theorem, the whole in itself is indeed a single thing, and is exempt from direct distribution into parts: it is 'imparticipable'. Thus, we arrive at the threesome imparticipable-participated-participant. Because Proclus is dealing with a metaphysical order where the attribute is more perfect and real than its subject (which is defined, and thus perfected, by it), he further distinguishes between a participated attribute that is complete and reified in itself (called 'self-hypostasized'), and a participated that must be always within a participant to accomplish this (such attributes are called 'image' and 'trace'). Between the fully transcendent ('imparticipable') and the fully immanent stands the sovereign immanent. This intermediary is the linchpin of Proclus' account. It refers to objective realities (for example, cosmic bodies, certain universal forces and properties, spirits) that are within reach of our apprehension but independent of us.

The constant 'flow' from unity to plurality, Proclus calls 'procession'. It leaves the source 'remaining' undiminished. The thing that 'proceeds' has its character diluted and altered by the conditions it is found in (for

example, Life itself becomes life of intellect, or life of plants). However, what ‘descends’ into plurality never severs its connection with its original, pure state, otherwise it would completely lose its definition (that is, the life of plant is still a life, not a plant-part). ‘Reversion’ is the tendency or movement to regain the lost pure definition (which is ‘remaining’ unaltered). These three are not discrete static states, but three distinguishable moments of a single dynamic process; practically everything undergoes all of them (with the One in a controversial position). For Proclus the three apply to every form, property or entity, not just to the conscious soul or cosmic strata of being (see Plotinus §3).

3 Levels

Things are composed of layers of qualities from corresponding degrees of reality. The various degrees are also modes because they modify any form, property or entity ‘in the manner proper to each’. (This is the philosophical reason for the high number of peculiar adverbials in the vocabulary of Proclus and later Neoplatonists.) The grades are bunched into broad levels (in addition to unity), typically: real existence, life, intellect, soul, physicality and body. (Principal classical sources are Plato’s *Sophist*, *Philebus*, *Parmenides*, *Timaeus*; see Plato §§15-16.) Each level has its ‘imparticipable monad’, followed by the multitude that is participated in: for example, Intellect and intellects. Moving from one level to another involves a substantive change, a ‘decrease’ (*hyphesis*) or an ‘elevation’ (*anagōgē*). Properties accumulate successively: real existence has unity, life has real existence and unity, intellect has life, real existence, and unity, and so on. So the ‘elevation’ also brings an analytical reduction to first principles.

Proclus arranges the levels of being by degree of perfection (completion) and by generality (*Platonic Theology* III 20-6), which is an inversion of Aristotle’s scheme of values. Soul is superior to body because it perfects it. Intellect perfects the soul, but is also more general because even animals have ‘a trace of cognition’. Life is superior to intellect because it is more general (even plants have it) and there cannot be a lifeless intellect. Being is, likewise, superior again because even inanimates have it. The rule - first by dint of being more general, derives from Proclus’ whole-part theorem (see also §6).

4 The One, the Good and the divine

The greatest unity, the ‘One’, transcends every possible attribution positive or negative, and so cannot be understood directly. It even transcends the very state of existence (see Plato, *Republic* 509b), so Proclus calls it ‘not being’ (*Elements of Theology* proposition 138), in the sense of prior to existent. This absolute metaphysical state coincides with that of value, since unqualified unity is the ultimate perfection (completion) desired by all. The One is identical to the Good and, as the supreme perfection, value and cause, is God. As fully imparticipable, God is transcendent, unknowable and ineffable. As the unity essential to everything that exists, the divine spark is immanent even in the lowliest material (see *Elements of Theology* proposition 145). However, Proclus carefully distinguishes divinity proper from deification by participation (for example, a divine body). Properly divine are only the One and the ‘self-hypostasized’ unities (see the discussion on *henads* given below), and by extension those entities predicated by such a unity (*Elements of Theology* proposition 114). The unknowable, supra-rational divine can be approached intellectually by stripping away attributions (known in Christian theology as the apophatic way to God), or by analogy, inferring what the One is like by its known effects. Ultimately individuals can reach the One by placing their faith in it with their own immanent ‘one’ during theurgical and mystical acts (see Chaldaean Oracles; Iamblichus).

But such extreme transcendence is almost self-defeating. How can the One and Good relate at all to existence? Proclus rejected Iamblichus’ two Ones (the fully transcendent and the causal). This still left the two fundamental problems (parallel to those faced, say, by modern big-bang cosmologists): How is existence produced from pre-existence? How does diversity arise from absolute simplicity? In answer to the first Proclus emphasizes the reified principles Limit and Unlimited (and Providence). In the second, he distinguishes the plurality of ‘ones’, the ‘henads’.

The One is essentially a limit, for there is nothing else except it. This also means that the One has no boundary imposed upon it (by something else): it is unlimited in potency. Limit and the Unlimited become the starting points of the chain of causation that produces the levels of being. Limit supplies definition and discreteness, and the Unlimited the ‘overflowing’ capacity to exist in continuity. The third factor is the providential activity of the One,

which reaches down to individual beings and perfects them with unity. Moreover, if the One is the prototype of oneness, then it must be the head of many participated 'ones', the 'henads'. A 'henad' is the very unity at the core of every existent, and there are as many henads as things that exist. Strictly the henads originate in the Limit, Unlimited and Providence, and so carry the seeds of differentiation at the root of the individual variety of things. Proclus distinguishes further the 'self-hypostasized henads' which belong to timeless or everlasting entities, the sort that tend to be worshipped as gods by diverse religions. The plain henads are the ones immanent in humans, animals, plants, minerals, and so on.

5 Intelligibles and soul

The highest level thought can reach is real existence, or pure being, the first broad category of the intelligibles. This is the object of thought (*noēton*) (the One is beyond thought). Here the contents of the One acquire their first layer of manifestation, in that they become 'really existent' and accessible to contemplation. Appropriately Proclus considers this to be the place of the universal pattern, the 'paradigm' (Plato, *Timaeus* 31a) and of eternity. Next he finds a middle intelligible level proper to pure Life, long before it is embodied in living beings. This stands for the capacity to multiply the contents of the whole. At the last intelligible level, the intellective (*noeron*), is Intellect itself (*nous*) (see Nous). From here and above we conceive things directly, as by intuition. The Intellect's essence is 'pure mind' (as embodied in the god Cronos in Plato, *Cratylus* 396b), whose contents are made distinct by the power of Intellect, identified with Rhea (*Cratylus* 402) and the 'Goddess' of the Chaldaean Oracles. The active exercise of Intellect results in the creative conception of things (*poiētikon*) (Plato, *Timaeus* 28c; Aristotle, *On the Soul* 430a12). Creative Intellect is God the Maker (Plato, *Timaeus* 29d-30c), who gives determinate form to the physical world. The Creator is well distinguished from the One - in sharp contrast with Christian doctrine. Intellect has polar outlooks: one contemplates the higher intelligibles and has intellective ideas and forms; the other is involved in producing time, soul and the physical things of ordinary experience.

Soul is what makes a body alive and 'is a substance between the really existent and becoming' (*Commentary on Plato's Timaeus* III 254.13-17). In the Platonic tradition soul straddles two domains: one is intelligible and beyond the bound of time; the other is physical and constrained by body, space and time. Proclus thus defines the soul's essence as atemporal but its activity as operating in time, because it cannot actualize all of its contents at once but has to unroll them onto the passing time. He distinguishes the 'imparticipable monad' of soul, which lies 'above the (physical) world' (*hyperkosmios*) and is associated with no body. The traditional Platonic world-soul (what moves the cosmos in the determinate way measured by science), although just as singular, now becomes a participated soul, whose body is the whole corporeal universe.

6 Body, matter and the One

The qualities characteristic of a body are said to be its nature (*physis*). In living beings nature is the instinctive, non-rational aspect of life, which is inseparable from the functions of body. It can be distinguished from soul proper (which is purposeful and separable) and from pure body (which is itself passive). However such distinctions are not always needed and so nature is often grouped with soul or body. An 'imparticipable' Nature is paradoxical (How can it be apart from a body?), which may explain why Proclus does not explicitly attribute to it the 'henads above and in the (physical) world' (*Platonic Theology* VI); although the link can be confirmed from diverse cross-references. Nature has the Necessity which determines physical behaviour. Indeed Nature's activity creates bodies directly, and seems also to be the monadic source of Body: there is no imparticipable body.

Body considered in itself is the last of things that exist in some sense. It is completely inert. Living beings move because of their vitality and inanimates according to their nature. For Proclus pure body is a quantity of a certain shape with three-dimensional extension. Matter, on the other hand, is not even a definite being, just the potential for something to be what it is.

At the low end of the metaphysical scale, entities become progressively less compound. There are living beings without a spark of intellect (plants), inanimates lack life, and matter lacks even determinate being. This is a result of the 'Proclean canon' that the more general and perfect the cause is, the further its extent of power. At the lower ranks, things receive attributes solely of the more general kind, not general *and* specific ones. Properties compound until the maximum number in the bundle is reached around the level of appearances that humans inhabit. From there, specific properties gradually diminish. So we arrive at simplicity in two different ways: in the superior sense

is the One; in the inferior is matter.

For Proclus this makes matter one continuous, universal power, and a direct extension of the One's Unlimited (in contrast to Plotinus' bisection of matter into intelligible and sensible). Matter is indeed to a degree good and of value. Like the One, it is most obscure and formless: the One is prior to intelligible definition, and matter beyond its reach. This does not mean, however, that Proclus considered material objects a short-cut to the One. 'Reversion' to the One is an 'elevation' through levels of being in the maximal sense, those with perfected properties.

7 Evil?

Proclus rejects completely the existence of evil as something absolute. He cannot find it in any of the levels of being, not even in matter which 'is in some way good'. Everything, including matter, has its roots in the One, which is Good. If there were a source for evil (Plutarch of Chaeronea (§3) blamed an evil world-soul, Gnostics the Maker, and Christians the devil) it would have to be 'beyond even the total lack of existence…further than the nothingness of non-existence' (*Commentary on Plato's Timaeus* I 374.14-17). What is commonly described as evil points to a relative weakness of the good: for example, when something is unnatural, or when it is bad for its purpose or deficient in some way (I 375, 381); in human actions, when the perpetrators are ignorant of what is best, and have a weak mind and soul (*On Evil* 50, 40-6).

Since evil is a parasitic and fictitious existence (*parhypostasis*) (*Platonic Theology* I 84-5), the only real choice open is the pursuit of the Good. This we fail to attain because of ignorance, inadequacies, selfish passions and a host of other restrictions. Freedom of action, therefore, means primarily to be free of such obstacles as inhibit or distort an individual's inherent desire to pursue the good.

8 Psychology

Psychē (usually translated as soul) is an alive, cognitive substance, as individual as the creature that has it. 'Mind' is a useful translation when contrasted with the perfect 'intellect' (*nous*), which stands above the partialities of soul. Every soul can cause spontaneous movement. The differences lie mainly in the way such movement is prompted and maintained by the soul's mental faculties. Animal *psychē* is simple. It is non-rational only, and concerned with sense-perception and appetites, although it still has a spark of intelligence. Human soul mixes rational and non-rational aspects (not parts because the soul itself is undivided). Thus, humans can lead a wide range of lives depending on how much they allow one aspect to control the other. Reflecting the complexity of its constitution, the human mind/soul has many faculties or 'powers'.

The non-rational side of the soul deals with input from the physical world. With sense-perception (*aisthēsis*) the soul receives the sensible qualities of material objects through the sensory organs. The diverse impressions, 'affections', are first organized into a unified impression. Next, with its opinion-forming faculty (*doxa*), the soul produces basic beliefs from the sensory evidence and any judgment about the source of these sense-impressions. Finally it visualizes things internally with its image-making faculty (*phantasia*).

The rational side of the soul deals with the outpourings from the intellect. Using its highest faculty, called *logos* (a word with many meanings (see Logos), but in this context signifying reason, definition and modelling), the individual mind has access to the 'inexhaustible supply' of ideas and inspirations. But being particular, the human mind admits them fragmented (not as intellective wholes). Soul has also its own concepts: '*psychē* was never a *tabula rasa* but is a tablet that has always been inscribed and is always writing itself and being written on by *nous*' (*Commentary on the First Book of Euclid's Elements* 16.8-10). Understanding is the result of the mental debate between successive arguments and propositions: that is, it is the result of 'discursive' reasoning. To compare the various concepts, the rational soul seems to employ its own imagination (*phantasia*), and sees representations of concepts as projections on the mind's screen from internal and external sources. By matching representations soul can complete or correct the impressions from the senses.

9 Soul and body

The individual soul, being particular, is incomplete and imperfect: it knows this and desires other things to complete it. Half-knowledge brings a sense of daring (*tolmē*), which results in the soul's total descent into body (in

contrast to Plotinus, who allowed a part to remain undescended). Once in the 'oyster shell' of the body it longs for proper completion and unification. From here the soul can be elevated, 'be saved', in three complementary ways, aided by the appropriate teachers and guiding spirits. With erotic love it strives to unite with the higher life (as in Plato's *Symposium*). With philosophical contemplation it reaches the intelligibles and speculates on the first principles. With theurgy (see Chaldaean Oracles; Iamblichus) it culminates in the leap of faith (*pistis*), which unites the soul's own 'one-henad' with the all-perfect One. The particular soul, through not knowing its place, can thus descend and ascend indefinitely through all the levels of thought and being (*Elements of Theology* proposition 206). This 'travel' is ontological when it involves the cycle of birth and death, and epistemological when the mind engages in lower or higher pursuits during a lifetime.

'Body' has several senses for Proclus. At its simplest it is pure space-extension, like a body of intangible light. Endowed with layers of qualities it becomes the physical body of our sensory experience. When soul descends into participation, it acquires a series of bodies, referred to as 'vehicles' (*ochēmata*). Every participated soul has at first a tenuous, 'luminous' body-vehicle (for example, the world-soul has universal space). However, any soul that descends further into the physical domain acquires a further vehicle composed of the four elements, fire, air, water, earth. Finally, those that incarnate on earth (for example, humans) acquire their particular fleshly body. So soul-types suit their degree of participation in body (consistent with the overall metaphysics). The vehicles played an important part in religion. After death the soul is purified by shedding its non-rational nature and the associated elemental vehicle. It is left free to ascend with its luminous vehicle.

Since the essence of human life resides in an immortal soul, which is separable from the physical body, Proclus adheres to the Pythagorean-Platonic doctrine of transmigration of soul (see Plato §11; Pythagoras §2; Pythagoreanism §3; Psychē). However, he does not believe that a soul can reincarnate backwards in the evolutionary scale towards full consciousness. References to reincarnations of humans in animals (Plato, *Timaeus* 42b-c), for Proclus, have sense if taken psychologically, not biologically: that is, a human can lead the life of a wolf (if unjust) or an ass (if gluttonous) but cannot be reincarnated as an actual wolf or ass.

10 Philosophy of science

Proclus' deep interest in the nature of reality includes the physical world and its scientific description by mathematics. He was familiar with practical and empirical science. In his main astronomical work, *Outline of Astronomical Hypotheses*, he describes the construction of a spherical astrolabe. He himself made some of the last reliable astronomical observations of antiquity (AD 475), and instilled this interest in Ammonius, son of Hermeas and Heliodorus.

Proclus' theory of knowledge is linked to his metaphysics of graded being, so instead of the division into rationalism and empiricism he has degrees of knowledge dependent mainly on the level of consciousness and awareness of the thinker (and on the kind of being the object of thought is). The clearest kind of knowledge is reserved for the non-discursive contemplation proper to the intelligibles, where realities are perceived directly and complete, as by intuition. Knowledge of the physical world falls below this, for it combines discursive reasoning with sensory perception.

What arises from sensation is contingent and frequently confused. It is an opinion (*doxa*). Discursive reasoning (*dianoia*) uses concepts to define things, and to correct sensory evidence (as in the apparent smallness of the sun due to the distance from the observer). Scientific knowledge results from the reasoning activity of the soul, which matches sensory-derived opinions with concepts, according to positive criteria for truth: syllogistically demonstrable proof, and correspondence to (metaphysical) reality.

Proclus' applications of his theory of scientific knowledge are most evident in his philosophy of astronomy, and specifically in his rejection of Ptolemaic cosmology (in which he stands unique until the Renaissance) (see Ptolemy). Two remarkable examples can be summarized. Proclus rejects the precession: not the precession of the equinoxes as we now understand the phenomenon, but Ptolemy's interpretation of it as a movement of all the fixed stars. For Proclus, such stars cannot precess because it is in their nature to be fixed, and those who claim that their observations fit the hypotheses fall foul of the false-false-true Aristotelian syllogism (for instance, premises: dogs are blue, blue things bark; conclusion: dogs bark). He denies that the planets are moved by nested heavenly spheres (a doctrine that dominated European astronomy until the sixteenth century) because the arguments for

them he finds to be conjectures, not necessary and demonstrable proofs, and because the celestial bodies are ontologically capable of moving by themselves in free space.

Proclus' philosophy of physics also marks a radical turn away from Aristotle on two key fronts: the elements of the physical world, and place as space. He rejects as *ad hoc* and superfluous Aristotle's fifth element for the heavens, the aether. The celestial bodies consist of the same (four) elements as the terrestrial. For instance, without a kind of fire the stars and the sun could not illuminate, and without a solid bit of earth-element they could not be opaque (as during eclipses). Employing his metaphysics of graded being, Proclus distinguishes the heavenly mode from the terrestrial: in the former, the elements are in their 'summits', for example, fire is purely illuminating, earth is purely tangible and opaque; in the latter, they are gross, for example, fire burns, earth is heavy. Furthermore, he develops a new account of the primary properties of the elements, which he derives from the size, shape and facility for motion of their particles.

The place a body occupies is not its boundary, as Aristotle stated. Proclus uniquely proposes that it must also be a kind of body, but without the mass that makes physical bodies resist each others' presence. It is three-dimensional space. By extension there is a cosmic space in which all the bodies of the universe are immersed. Space on its own, apart from the bodies that move in it, is like a body of light.

As to mathematics, Proclus rejects Aristotle's view that mathematical objects (numbers, points, lines, proportions and so on) are abstractions from physical things, and develops the Platonic argument that they exist independently of human experience, but without the inscrutability of Forms. Mathematicals have dimensions, occupy relative places, are many in number within each kind, and so share some of the features of physicality. They dwell in the mental essence of soul, but without dimension. Soul 'projects' them onto its imagination, as onto a screen, where they acquire their familiar dimensionality (*Commentary on the First Book of Euclid's Elements* 50-2). Thus mathematical knowledge is a mixture of reasoning and imagination. The mathematical study of bodies (mechanics, optics, astronomy) relies on holding particular images more than the study of shape in general (geometry). The study of numbers relies on it much less and therefore is closer to pure reasoning. Above all stands the study of rules and relations, of analysis and synthesis. Ultimately the objects of mathematics originate in the Limit-Unlimited of the One. Mathematics is a bridge between sensory perception and the most complete state of knowledge. Thus in education, mathematical study prepares the mind to apprehend the pure realities.

11 Influence

Through his students (for example, Ammonius) and writings, Proclus influenced later Greek philosophy at its two leading centres, Athens and Alexandria, until the end of antiquity in the seventh century. His metaphysical system was adopted by Pseudo-Dionysius the Areopagite for a Christian celestial hierarchy. In turn, this influenced both Byzantine thinkers (Maximus Confessor, John of Damascus) and those of the Latin West (see Eriugena, J.S.; Grosseteste, R.). Islamic theologians of the tenth century, such as the Ikhwan al Safa', were inspired by Proclus' emanationism and theory of mathematicals (see Ikhwan al Safa'; Neoplatonism in Islamic philosophy). Furthermore, Arab scholars produced a compilation of his *Elements of Theology* under an Aristotelian label. Thomas Aquinas (§7) was the first to detect that Proclus was the author of the doctrines in all these works. Aquinas' friend William of Moerbeke rendered the first Latin translations of Proclus' main works. A new wave of Proclus' direct influence arrives in eleventh- to fifteenth-century Byzantium, and in Humanist Europe, notably with Ficino and Nicholas of Cusa. From there, Proclus' philosophy and science can be found in Kepler, the Cambridge Platonists (see Cambridge Platonism), Spinoza, the English Romantics, Cousin, and in various philosophers of idealism, culminating with Hegel (see Idealism; Hegel, G.W.F.).

LUCAS SIORVANES

List of works

We cannot date Proclus' writings (many of which were based on lecture-courses) because he continued making additions after initial publication. The *Platonic Theology* seems to be his last major work. There are student's excerpts of the commentary on Plato's *Cratylus*, but commentaries on Plato's *Theaetetus*, *Philebus*, *Sophist*, *Phaedo*, *Phaedrus*, *Symposium* and on Aristotle's logic have not survived; on Plotinus there is only a tiny portion. In nineteenth-century London, Thomas Taylor, who influenced the Romantics, translated most of Proclus' works. However, the translations of modern, reliable editions of Greek texts are mainly in French or German (as are many

of the studies).
Proclus (mid 5th century AD) *The Elements of Physics* or *On Motion*, ed. A. Ritzenfeld, *Institutio physica*, Leipzig: Teubner, 1912; trans. T. Taylor, 1831.(The former is a parallel Greek text and German translation, the latter an English translation; the text has no Neoplatonic theorems but is a short study manual on Aristotle's *Physics* books VI and VII and *On the Heavens* book I.)
Proclus (mid 5th century AD) *The Elements of Theology*, ed. and trans. E.R. Dodds, Oxford: Clarendon Press, 2nd edn, 1963; repr. 1992.(Systematic study manual of Proclus' Neoplatonism.)
Proclus (mid 5th century AD) *On Providence*, ed. D. Isaac, *Dix problèmes concernant la providence*, Paris: Les Belles Lettres, 1977; trans. T. Taylor, 1833; repr. Frome: Prometheus Trust, 1998.(Isaac has parallel Greek text and French translation; Taylor's English translation also includes *On Fate*, and *On Evil*.)
Proclus (mid 5th century AD) *On Fate*, ed. D. Isaac, *Providence, Fatalité, Liberté* Paris: Les Belles Lettres, 1979. (Parallel Greek text and French translation.)
(mid 5th century AD) *On Evil*, ed. D. Isaac, *De l' existence du Mal*, Paris: Les Belles Lettres, 1982.(Parallel Greek text and French translation.)
Proclus (mid 5th century AD) *A Commentary on the First Book of Euclid's Elements*, ed. G. Friedlein, *In primum Euclidis elementorum librum commentarii*, Leipzig: Teubner, 1873; trans. G.R. Morrow, Princeton, NJ: Princeton University Press, 1970; repr. 1992.(Morrow is English translation of the 1873 text.)
Proclus (mid 5th century AD) *Commentary on Plato's Republic*, trans. A.J. Festugière, *Proclus Commentaire sur la République*, Paris: Vrin, 1970.(French translation.)
Proclus (mid 5th century AD) *Commentary on Plato's Timaeus*, ed. E. Diehl, *In Platonis Timaeum commentaria*, Leipzig: Teubner, 1903-6, 3 vols; repr. Amsterdam: Hakkert, 1965; trans. A.J. Festugière, *Proclus Commentaire sur le Timée*, Paris: Vrin, 1966-8, 5 vols; trans. T. Taylor, London, 1810; repr. Hastings: Chthonios Books, 1988; repr. Frome: Prometheus Trust, 1998.(Festugière provides a parallel Greek text and French translation; Taylor is a reprint of his 1810 English translation.)
Proclus (late 5th century AD) *Outline of the Astronomical Hypotheses*, ed. C. Manitius: *Hypotyposis astronomicarum positionum*, Leipzig: Teubner, 1909; repr. Stuttgart, 1974.(Parallel Greek text and German translation.)
(late 5th century AD) *Commentary on Plato's Alcibiades I*, trans. W.O. Neill, The Hague: Martinus Nijhoff, 1971; ed. A.Ph. Segonds, *Sur le premier Alcibiade de Platon*, Paris: Les Belles Lettres, 1985-6.(The former is an English translation, with commentary, the latter a parallel Greek text and French translation.)
Proclus (late 5th century AD) *Commentary on Plato's Parmenides*, ed. V. Cousin, *In Platonis Parmenidem*; Paris: Durand, 1864; repr. Hildersheim: Olms, 1961; trans. J.M. Dillon and G.R. Morrow, *Proclus' Commentary on Plato's Parmenides*, Princeton, NJ: Princeton University Press, 1987; repr. 1992.(Book 7 is preserved in a Latin rendering by W. Moerbeke, recovered by R. Klibansky and L. Labowsky, London 1953, published in a revised edition (ed.) C. Steel, *Commentaire sur le Parmenide de Platon*, 2 vols, Leuven: Leuven University Press, 1982-5; with introduction.)
Proclus (late 5th century AD) *Platonic Theology*, ed. H.D. Saffrey and L.G. Westerink, *Théologie platonicienne*, Paris: Les Belles Lettres, 1968-97; trans. T. Taylor, *The Platonic Theology in Six Books*, London, 1816; repr. New York: Selene Books, 1985-6.(The former is a parallel Greek text and French translation, the latter a reprint of Taylor's 1816 translation.).

Prodicus (*fl.* late 5th century BC)

Prodicus was a Greek Sophist from the island of Ceos; he was active in Athens. He served his city as ambassador and also became prominent as a professional educator. He taught natural philosophy, ethics, and of course rhetoric, but he is best known as an authority on correct language, specializing in fine verbal distinctions. Prodicus' greatest influence was due to his naturalistic interpretation of the traditional Greek gods; as a result, he later figured on the short list of famous atheists.

Prodicus came to Athens on public business as representative of his native Ceos, and seems to have settled there permanently as a professional teacher, earning large sums from his course of instruction. By 423 BC he was famous enough to be mocked by Aristophanes in his comedy the *Clouds*, together with Socrates, as a teacher of natural philosophy (*Clouds* 360-1; A5). The Platonic Socrates claims to have heard Prodicus lecture on language, although he could only afford the cheap, one-drachma course, not the deluxe course for fifty drachmas (Plato, *Cratylus* 384b). And Socrates says that he frequently sends students to Prodicus who do not seem apt to profit from associating with himself (Plato, *Theaetetus* 151b). Prodicus is cited in Plato's dialogues as an authority on 'the correctness of names'. Plato has made him a figure of fun by representing him as insisting upon fine distinctions between near synonyms such as 'pleasure' and 'enjoyment', 'wanting' and 'desiring' (see, for example, Plato, *Protagoras* 337a-c, 340a).

Prodicus was author of a book entitled *Hōrai (Seasons)* from which Xenophon (*Memorabilia* II 1.21-34) has extracted a long quotation or paraphrase known as the 'Choice of Heracles'. In this text two allegorical figures, women named Virtue and Vice, present Heracles with alternative paths to happiness, one of which is short and easy, while the other is long and arduous (Xenophon, *Memorabilia*, II. 1.21-34; fr.2). The rhetoric is picturesque, the morality is predictable, but the allegory became extremely influential.

The most interesting philosophical contribution of Prodicus was a naturalistic theory of the origin of religion (fr.5). According to Sextus Empiricus, Prodicus claimed that 'the ancients considered that sun, moon, rivers and springs, and generally all things beneficial for our lives, are gods because of their usefulness'. Other reports suggest that the development of agriculture played an important role in Prodicus' explanation, and that names like Demeter and Dionysus were said to reflect the invention of bread and wine. According to several authors, Prodicus denied the existence of the traditional Greek gods. If this is correct, his theory would be more anthropological than allegorical.

Prodicus' explanation of the origin of religion apparently presupposes a more general account of the evolution of human culture from primitive beginnings, when the life of mankind was like that of beasts. This account in turn belongs in a larger cosmological context: the attempt of Ionian natural philosophy to explain how the current world order developed from a more primitive state of affairs 'in the beginning'. The rise of human civilization is the final chapter in Presocratic cosmogony, as we find it more fully reproduced in later authors such as Lucretius.

Prodicus' explanation of Demeter and Dionysus as inventors of bread and wine is echoed in Euripides' *Bacchae* (274-85), where it is used to justify the worship of Dionysus. Since we do not have Prodicus' own words, it is difficult to know how far his theory is compatible with the allegorical practice by which later philosophers preserved respect for the civic cult by reinterpreting the traditional gods in more scientific terms. Like the evolutionary account, the allegorical interpretation is older than Prodicus. Thus Metrodorus of Lampsacus and other followers of Anaxagoras will identify Zeus with intelligence (*nous*), Athena with art or craft (*technē*), Achilles with the sun, Hector with the moon, and so on (A4 and 6). Diogenes of Apollonia is reported to have identified Zeus with cosmic intelligence in the form of air (see Diogenes of Apollonia §2). It was this type of allegory that became conventional (Apollo as the sun, Artemis as the moon, Athena as wisdom, and so on) and was later developed systematically by Stoicism. According to some scholars, Prodicus belongs in this tradition.

If the report of atheism is correct, however, Prodicus was concerned only to explain and not to justify the worship of the gods. The relevant parallel would be what we find in the *Sisyphus* fragment (fr.25 variously attributed to Euripides and to Critias), where the invention of the gods is described as the device introduced by a clever man in order to enforce morality. A similar cultural prehistory must lie behind the fragment 30 of Democritus (compare

Democritus §4), that claims that 'a few learned people raised their hands on high and called the Air "Zeus"'. Prodicus' theory was apparently more elaborate. He seems to have distinguished two stages in the development of religion. In the earlier stage human beings began to worship the forces of nature on which they depended: sun, rivers, springs, and things useful for life. In the next stage, moving from the state of nature, they deified cultural heroes and heroines who invented agriculture and useful arts: Demeter, Dionysus, Athena and the like were divinized mortals, like Heracles and Asclepius. On this view, Prodicus is the author of the theory of religion later known as Euhemerism, which claims that the gods were originally human beings who were deified because of their great achievements.

Professional ethics

Professional ethics is concerned with the values appropriate to certain kinds of occupational activity, such as medicine and law, which have been defined traditionally in terms of a body of knowledge and an ideal of service to the community; and in which individual professionals have a high degree of autonomy in their practice. The class of occupations aiming to achieve recognition as professions has increased to include, for example, nursing, while at the same time social and political developments have led to criticism of and challenge to the concepts of professions and professionalism. Problems in professional ethics include both regulation of the professional-client relationship and the role and status of professions in society. A central question for ethics is whether there are values or virtues specific to particular professions or whether the standards of ordinary morality are applicable.

1 What is a profession?

The term ‘profession’ is used in different senses. In a wide sense it simply means someone’s occupation; in a narrower sense it refers to a certain kind of activity, one carrying with it a certain status and associated with a particular ethic. Traditionally a profession has been marked out by a body of knowledge, mastery of which (at least partly) regulated entrance to its ranks; and by an ideal of service (see Airaksinen 1994). Since the body of knowledge had the potential to confer power, money and status, professionals were expected to use their skills for the benefit of the community. Those groups which have long been secure in their recognition as professions, the so-called liberal or learned professions such as medicine, divinity and the law, have also been characterized by a considerable degree of authority and autonomy in their practice. The epithet ‘liberal’ emphasized their suitability for the ‘free man’; ‘learned’ brought out their relationship to a body of knowledge. The fact that professionals are said to ‘practise’ rather than ‘work’ is itself significant in reinforcing their autonomy and status. Along with the autonomy of the individual professional, professional bodies have also been accorded a significant degree of autonomy in controlling both access to the profession and professional conduct.

Eliot Freidson (1994) outlines the problems of defining ‘profession’ in terms of a number of characteristics or traits and considers instead a definition in terms of process, that is, how particular occupational groups gain professional status. He argues, however, that this covertly defines a profession as an occupation that has gained professional status. Freidson’s view is that the concept of ‘profession’ is one that is tied to particular socio-cultural conditions, namely Anglo-American industrial nations which associate status with occupation, rather than with education, as is more common, he claims, in other European countries.

The traditional classification of professions has been subject to two contrasting trends: first, the attempt by some groups for recognition as professions or neo-professions; and second, challenge to the notion of professionalism either because of its conceptual inadequacy, as noted by Freidson, or on the grounds of its social consequences.

Nursing is a prominent example of an activity which has aimed at recognition as a profession, in its struggle to distance nurses from the image of handmaiden and to advance towards their acceptance as accountable professionals (see Nursing ethics); to discard the metaphor of loyalty and take up that of advocacy (see Winslow 1984). In such struggles, the concepts of professional autonomy and accountability play a part along with the identification of a body of knowledge.

Coinciding with a move on the part of some groups to become recognized as professions, there has been a challenge to the concepts of ‘profession’ and ‘professionalism’, and an attempt to replace the focus on the concept of profession with one of a set of competences, in other words, to concentrate on what people do and achieve rather than on their status. One reason for this has been that critical, reflective professionals, with autonomy over their practice, may be seen as a threat (see Williams 1996). A second reason is connected with the potential for professions to become self-serving elites (see Freidson 1994; Illich 1977). Yet a third is the increase in criticism if not litigiousness of more knowledgeable clients. Williams contrasts the professional approach and the competence-based approach in the following way: ‘Competent workers are content to be described as such, and trainers do not try to push them any further, while reflective practitioners aspire to research their own practice and agencies’ (Williams 1996: 8).

What is not in dispute between the two approaches is an attempt to distance what is required from incompetence.

J.K. Davis (1991), for example, has argued that for professionals it would not be sufficient that a client was satisfied, if the professionals themselves felt that the service was below standard. For the professional, however, it is more than simply doing a competent job: a worker becomes a professional by professing reasons for doing their work in a certain way.

2 Professional ethics: the problems

Problems of professional ethics fall into two broad categories, but both arise essentially from professional power. The first is concerned with the professional-client relationship, while the second relates to the role of professions and professionals in society as a whole.

Although an ideal of service is supposed to provide a safeguard to promote the use of professional expertise to help rather than harm, specialist knowledge, to which professionals have access and clients do not, does give power to the professional, and the client is thus placed in a vulnerable position. One caveat however is that the paradigm of a relationship between two individuals is inadequate because it overlooks those professions which do not conform to this pattern, such as teaching, which may be but commonly is not done on a one-to-one basis (see Langan 1991).

The most thorough discussion of the professional-client relationship has taken place in relation to the medical profession, with regard both to the feasibility of applying traditional ethical theories to the problems of medical practice and to the development of a set of principles specific to the context of the relationship between health care professional and patient, as in Beauchamp and Childress' principles of biomedical ethics (1979) - autonomy, beneficence, nonmaleficence and justice. A question about the use of power in the medical context would be whether practitioners should use their expertise to decide, beneficently, what is in the patient's interest, or provide information to enable the patient to take an autonomous decision (see Medical ethics §2).

The second category of problems is more concerned with the role and image of professionals in society. While it may be true that there has always been a tendency towards distrust of professionals, this has been exacerbated by social and political developments (see Pellegrino 1991). The trend towards client autonomy, attempts by government to curb the independence and privilege of professionals, and media criticism have all had their effect. Darryl Koehn (1994) adds to this list the assault of academic disciplines such as sociology and philosophy. The sociological critique has suggested that professions, rather than being essentially moral enterprises, are in fact effective monopolistic institutions and that the professed commitment to ethical ideals, rather than conferring legitimacy on the profession, is nothing more than ideology. Ivan Illich has termed the mid-twentieth century the age of 'disabling' professions: far from using their knowledge to serve, they have become forms of control, claiming the authority to determine human needs. 'Homes are transformed into hygienic apartments where one cannot be born, cannot be sick and cannot die decently' (Illich 1977: 27).

Philosophers have taken issue with a self-derived ethic which permits professionals to be guided by standards other than those of ordinary morality. 'Problems in professional ethics typically arise when the values dominant within particular professions come into conflict with other values in the course of practice. Professionals are likely to perceive these values as dominant where others may not' (Goldman 1992: 1018). The possibility of self-derivation is linked with the autonomy of professional bodies in determining standards of practice. A self-derived ethic might take one of two forms. In one form it is associated with the idea that there are certain ways of behaving appropriate to different roles, which diverge from those suited to people who do not fill that role. For example, it might be argued that a lawyer is under an obligation, arising out of the lawyer's role, to achieve the best result for a client even if that conflicts with what they believe as a private individual.

> I remember a custody case for a most disagreeable man whose wife had left him with the children. I remember reducing her to floods of tears in the witness box and I felt very badly about it because I thought she was a very nice woman, which she was, and her husband was a shit. On professional grounds I knew I had done a really good job. But as a father of young children I really thought that the right result hadn't been achieved.
>
> (Quoted in Chadwick 1991)

It is possible to interpret this quotation in different ways. It might be seen either as a clash between professional standards and 'ordinary' morality, or as a conflict between two different moral viewpoints: the view that one's duty is to see justice done and the view that one's duty is to the client and the court.

The second form in which a self-derived ethic might find expression is in a code of professional conduct or code of ethics. The possession of a code of professional conduct has been pivotal in debates about what constitutes a profession. Such a code can fulfil a variety of functions (see Chadwick 1992): offering a public statement of ideals and values; providing a disciplinary mechanism for a professional body; reassuring the public that the profession upholds certain standards; and educating members of the profession to 'think like' others in the group (see Davis, M. 1991).

The standards incorporated in a code may be either higher or lower than the standards of ordinary morality. Professionals have traditionally been prevented from doing things which people in other spheres of activity are permitted to do, such as advertising. This arises out of the purported commitment to serve first the interests of clients, rather than their own profit. On the other hand this same commitment can act as a shield to protect professionals from the criticism that they do things which would be frowned on in terms of ordinary morality, such as lying to clients or physically hurting them in order to promote some further end identifiable as being in the client's interests (see Hayry and Hayry 1994).

Criticism of a self-derived professional ethic, whether in the form of role ethics or a code of conduct, is based on arguments that if an action is morally right it should be susceptible of justification by the same moral arguments that apply to the behaviour of any other member of society - professionals should not require special ethical norms to be determined by themselves. For it is not clear how such norms could be justified if not by common moral principles (see Goldman 1992).

If this point is accepted, however, there are arguments in favour of having, if not a self-derived ethic, at least an ethic specific to a given professional group, in order to promote consistency among practitioners rather than leaving moral judgment to the fallible individual alone. Even if it is acknowledged that the individual practitioner has autonomy in their practice, the requirements of accountability and a set of defined standards has the result that the practitioner may literally be called to 'give an account' of themselves and their practice in terms that their professional peers will recognize (see Holdsworth 1994). This arguably affords more protection than the absence of professionally defined norms but does not constitute an argument for dispensing with accountability to society as well.

Sociological and philosophical criticism have constituted aspects of a phenomenon which might be called the challenge to the ethics of trust in the professions (see Trust). Traditionally the professional-client relationship has been regarded as a fiduciary one, in which the professional is worthy of trust and the client places trust in the professional. In the late 1980s and early 1990s, however, the ethics of trust was challenged. In the light of these challenges the question arises whether the appropriate response is to turn to an 'ethics of distrust' (see Pellegrino 1991). An ethic of distrust would proceed by attempting to regulate more closely the activities of professionals, by increased external monitoring and demands for accountability. According to one view this approach wins the day by default because the notion of an ethics of trust is not only difficult to sustain: it is actually incoherent.

Robert Veatch (1991) attacks what he sees as the three arguments supporting an ethic of trust: (1) that professionals serve the client's interest; (2) that professionals can present value-free facts to the client; and (3) that professionals should act on a set of virtues inherent in the profession. Veatch argues that modern professionals ought not to know what the client's interests really are - the most they can know is what the client's interests are in one particular area of life. Whereas medical professionals might be concerned primarily with promoting health, for example, health might not be the top priority for a patient (see Goldman 1992). Veatch also argues both that professionals cannot present value-free facts and that it is a serious mistake to think that any given profession is associated with one particular conception of virtue. For example, Talmudic and libertarian lawyers will be informed by different conceptions of the appropriate virtues.

A less pessimistic approach is to investigate the possibility of grounding trust in the professions anew. Koehn has argued that this is urgent because professions represent the mechanism chosen by Anglo-American morality for providing people with goods such as health and justice, and if professionals are not trustworthy, where are we to turn for help? For health and justice are not goods that are readily dispensed with. For Koehn, the challenge is to show not only that there are grounds for trust in the professions because they provide people with such goods, but also that they do not violate the requirements of ordinary morality.

3 Theoretical approaches: external and internal

How are the ethical questions to be addressed? The central issue seems to be the contrast between the external and internal perspectives. The external approach would be to take a normative theory, such as Kantianism or utilitarianism, and apply it to the issues arising in the professional-client encounter and the social role of professionals (see Kantian ethics; Utilitarianism). The alternative would be to examine whether, rather than applying such an external standard, there are values internal to particular professions. A feminist ethic of care could count as either external or internal according to how it was interpreted - whether, for example, an ethic of care provides a framework for addressing problems or whether it perceives care as a virtue inherent in certain professions (see Curzer 1993) (see Feminist ethics §1; Nursing ethics).

Providing an example of the application of an external theoretical framework, Richard Tur (1994) suggests that the standard conception of the lawyer's role arises from the political philosophy of liberalism with its neutrality concerning ideas of the good life, and is associated with the moral philosophy of utilitarianism (see Liberalism). The application of utilitarianism suggests both that the good lawyer is one who pursues the objectives of clients effectively, and that doing this under the adversarial system promotes the best interests of society as a whole. This is both because the adversarial system is justified in terms of facilitating the emergence of truth and because to allow individuals to pursue their own view of the good life will maximize social benefits.

The internal approach, on the other hand, might attempt to derive values internal to specific professions by examining the point of those professions. Rather than accepting them as Illich's 'dominant' professions that take it upon themselves to define human need, the question to ask is what pre-existing human need or value do and should they serve? This quest might take different forms. The identification of health and justice as goods that cannot readily be dispensed with, because they may be needed by vulnerable people, has been mentioned. Or there might be an argument for some intrinsic or 'transcendent' values embedded in a professional activity. In the case of law, Tur suggests innocence as an internal value that has implications for specific actions in practice - if innocence is non-negotiable then plea bargaining becomes unethical. Third, knowing the point of a practice such as a professional activity might point the way to virtues internal to the practice of that activity. The virtuous doctor and the virtuous lawyer will not need to apply an ethical theory such as engaging in a utilitarian calculation. As virtuous practitioners they will be able to see what is required in particular situations (see Virtue ethics; Virtues and vices).

On this view the virtues of a profession will be defined by reference to the meaning of the practice in question. This would facilitate an answer to the question, for example, of whether nursing ethics is distinct from medical ethics. The central issue that remains unresolved is whether the tension between a relativistic and a universalistic approach to professional ethics can be mediated by an appeal to the unity of the virtues in the moral life (see Meilander 1991) (see Moral relativism; Universalism in ethics).

Projectivism

'Projectivism' is used of philosophies that agree with Hume that 'the mind has a great propensity to spread itself on the world', that what is in fact an aspect of our own experience or of our own mental organization is treated as a feature of the objective order of things. Such philosophies distinguish between nature as it really is, and nature as we experience it as being. The way we experience it as being is thought of as partly a reflection or projection of our own natures. The projectivist might take as a motto the saying that beauty lies in the eye of the beholder, and seeks to develop the idea and explore its implications.

The theme is a constant in the arguments of the Greek sceptics, and becomes almost orthodox in the modern era. In Hume it is not only beauty that lies in the eye (or mind) of the beholder, but also virtue, and causation. In Kant the entire spatio-temporal order is not read from nature, but read into it as a reflection of the organization of our minds. In the twentieth century it has been especially non-cognitive and expressivist theories of ethics that have adopted the metaphor, it being fairly easy to see how we might externalize or project various sentiments and attitudes onto their objects. But causation, probability, necessity, the stances we take towards each other as persons, even the temporal order of events and the simplicity of scientific theory have also been candidates for projective treatment.

1 Mechanisms

Projective theories recognize the role of our own natures in shaping the judgments we make. They also promise useful metaphysical economies, by seeing us as responding to a world with less in it than is needed if we think that to every judgment there corresponds an independent property of things. They may therefore be motivated in a number of ways. On the side of metaphysics we may have concerns that if the real world is conceived in some special way, we introduce mysterious properties with equally mysterious relations to other properties. Or, we may have epistemological worries about the ways we know of the independent properties. On the side of the subject we might want to recognize that the judgments in question have special relations to action or motivation or emotion, and we might find this inexplicable if we see ourselves as simply cognizing an independent order of facts. Projectivism is therefore best seen as an explanatory theory, and accepting a projective theory itself manifests the commitment that some aspect of the world is not as independent of us as we might think.

Within the broad characterization there are many different accounts of the mechanisms of projection, of the consequences of a projective theory and of the method whereby we should assess whether a projective theory is appropriate in one area or another. Perhaps the most simple and forthright combination of doctrines would be that the mechanism is one of displacing, or relocating, what is in fact a feature of our experience, and making it into a feature of the world. The consequence is that we make a mistake, erroneously treating the world as containing features that it does not really contain (an error theory). The appropriate method is then to sift through the evidence that such a displacement actually occurs, and to decide whether we can live with the thought that some area of our judgment is thoroughly entangled in error. A theory of this form is found in the treatment of colour by Cartesian philosophers such as Malebranche and Arnauld. Colours are found only in the mind; the world itself is not coloured, but we naturally treat it as if it is. The answer to the question whether this makes God, who gives us this nature, a deceiver, is that it is good for us that we make the displacement, in the same way that it is good that we feel pains in our limbs: the mistake has a practical benefit. In more modern terms, colour vision is a useful adaptation to a world that is not coloured.

However, several features of this way of thinking may be questioned without departing from the projective model. We might deny that the mechanism is one of literal displacement. Perhaps the mind manages to make the world look as though some things have beauty, for example, without the really beautiful objects being in the mind itself; instead, some kind of pleasure or delight is objectified, it then appearing that there is a feature of things correlated with it. There would be no real or true bearer of beauty in the mental world but only the real, non-aesthetic properties of the object, the pleasure or delight that these arouse and the propensity we have to voice that pleasure by describing the object as beautiful. Theories of this tripartite kind are more commonly called projective in the contemporary idiom.

Historical examples include Spinoza's view that while everything is really necessary, we feel our own ignorance

when faced with the course of events and voice it by describing events as contingent. There is Hume's view that the real object of perception is the regular pattern of events, although faced with this we 'make no scruple' of foretelling one event upon the occurrence of another, and voice this by describing them as causally connected. There is equally Hume's view that, faced with some features of character such as temperance and cheerfulness, the mind feels a pleasure which it voices by deeming those features virtues. When we do this we 'gild or stain' objects with the 'colours borrowed from internal sentiment', and thereby 'erect in a manner a new creation' (see Hume, D.). In Kant, apart from what is said about space and time, there is his attitude to the judgment of beauty - that it essentially voices a felt delight, not prompted by a literal perception of beauty (see Kant, I.).

In the twentieth century, F.P. Ramsey and Bruno De Finetti held that talk of probabilities is a projection, not because events in the mental world are alone subject to probability, but because they saw such talk as voicing our degrees of confidence in response to observed frequencies of events. Also in Ramsey, to think of a regularity as a natural law is not to see it as somehow fixed by some special and mysterious locking device, but to give it a certain dignity as part of the system with which we meet the future. The emotive theory of ethics, designed to make a place for ethics despite its being neither empirical nor issuing in truths of logic, is a central example of the Humean approach (see Emotivism). Other examples occur in the works of the later Wittgenstein.

When something is described as nice, sublime, good or whatever, projective theories have traditionally found it important to locate the projected reaction, in the first instance, independently of describing it as 'whatever you feel'. If what you feel can only be identified as a tendency to make the judgment, then it is easy to think that no gain has been made. For if we are sincere, whenever we make a judgment we express a tendency to make the judgment. Seen this way there is an obligation on projectivists to identify the reaction in other terms: classic suggestions include a felt pleasure (lying behind judgments of beauty), a particular pressure on choice and action (behind ethical judgment), degrees of confidence (behind probabilities), willingness to rely on a regularity (behind seeing it as causal in nature) and so on.

2 Consequences

Each of the mechanisms outlined may suggest that some kind of error is involved. The stories bear some affinity to the familiar thought that an emotion may be incorrectly projected upon a thing, as when one nostalgically invests past events with an illusory glamour or perfection. However in the philosophical examples, it is not clear that we make any error when we project. We might think that we are deceived by our senses when we take the world as coloured, or by our passions when we take things to be beautiful, or by our degrees of confidence when we find events probable. But the alternative approach is that there is no question of error. All that is involved is a natural and desirable way of experiencing the world, and the fact that the categories involved have the projective explanation does not infect them with mistake. Discovering the mind-dependence of colours, for example, need not be presented as discovering that the world is not really coloured. It is just that the story behind the fact that it is coloured has its origin in the structure of our visual responses. To return to the analogy with the pain in the foot: it is not obviously an error to locate the pain in the foot (as it would be if the pain were really somewhere else, such as in the head).

If the metaphor of projection is dissociated from the idea of error, then it must be asked how much ordinary thought is compatible with the explanation. In ethics this question has proved especially controversial. To many writers it has seemed that the independent claim made on us by such things as moral obligation and duty becomes softened and lost if those categories are projections of attitudes or stances that we ourselves have taken up. The spectre arises that the explanation of the commitment in fact undermines it, so that there is a disharmony between ethics as it feels to the subject, and the philosophical appreciation of what it actually is. Others have argued that this is a mistake akin to worrying whether ethics is possible without God. There is no reason for the feeling of obligation to wane if it is revealed for what it is - a feeling - any more than there is reason for us to stop finding things funny when we recognize the subjective nature of that reaction. 'Quasi-realism' is a title invented to describe the attempt to reconcile projective theories with the appearances of independent (and even demanding) fact in such areas.

One focus for the kind of debate that arises is the notion of knowledge. It is frequently thought that a projective theory should deny that there is real knowledge to be had in an area. Thus a common title for the position is 'noncognitivism', and many projectivists have been content to accept it. However, if projectivism about colour

rejects the error theory, then it ought to be able to say not only that mail boxes in Britain are red, but that we know that they are. The force of saying this will be that there is no real possibility of an improved view of them, revealing that our original colour judgment was deficient - as it would be due to inadequate light, or a poor glimpse. Similarly in ethics, a projectivist may not only say that ingratitude is a vice, but that we know that ingratitude is a vice, again meaning that this judgment is secure enough for there to be no real chance of it being abandoned, whatever improvements in our moral sensibilities come about ('improvement' not meaning convergence on some antecedent truth, but simply better use of the virtues we already recognize: care, attention, imagination, sympathy). Once this is the landscape, it is hard to find simple ways of assessing projective theories.

3 A real debate?

Discontent may seize upon each of two dualisms, urging that projectivism magnifies the first, and the second is either underestimated or loses its identity as a distinct picture. The first is that of mind versus the world. In the case of colour, projectivism seems to depend upon this being a sharp division, with the issue being that of where the original place for colour is found - inside or outside, as it were. If projectivism in any area similarly depends upon separating how things are with one's mental life from how things are in the world, then it implies a highly controversial dualism, and may fall to a more unified picture of our lives in the world. This criticism may carry more weight in some areas than others. In the colour case, it may well be that proper attention to the way perception of colour, understood not as simply arousal of a sensation but as an engagement with the world, undermines the Cartesian story.

In the case of ethics, or modal judgment, or statements of law or probability, dualism does not seem to be the issue, since the non-representative nature of the basic responses is not a consequence of a split between mind and the world, but rather a consequence of distinguishing different aspects of the way we meet the world. This however introduces the second dualism, which is that of representation or description on one side, versus the reactions and responses that the projectivist needs to start with. Thus we have already touched on the apparent need for a projective theory to identify the reaction we project, at least initially, as something other than simply a judgment. But critics have frequently complained that the reactions cannot in fact be identified with the necessary precision without invoking the very vocabulary that needs to be avoided. For example, suppose we describe the state projected in making a positive ethical judgment as one of approval, the critic will say that approval is not a primitive feeling or sensation, but a highly complex state which is possible only to people already embedded in ethical practice. One reply is to say that we have enough grip of the primitive reactions (anger, guilt, willingness to succumb to pressure from others) in question to see our practices as based on them or developed out of them. Provided this rational reconstruction of the activity of moralizing is possible, a projectivist may grasp the nettle and put up with the apparent circularity: what is projected when we say that something is good may simply not be identifiable in any terms except those from the ethical family. Yet provided we can see how we got involved with this family, all may be well.

If the fundamental state of mind is not really one of making a judgment, then how can it properly acquire the trappings of judgment? A sharp form of this problem, originally aired by Frege, points to the numerous things we can do with judgments apart from voice them, and asks the projectivist to explain (see Frege, G.). For example, if saying that feminism is a good thing voices an attitude to feminism, what is said by 'if feminism is a good thing, we should employ more women' or 'feminism might be a good thing, but I am not sure', where no attitude is voiced? Although this problem has been attacked head-on, it is still often felt that a 'Fregean abyss' separates judgments with content from the projectivist's ingredients. On the other hand, if the abyss can be crossed, then one might worry about the point of starting with a non-representative response in the first place. Here again the projectivist need not give in, for even if our basic responses are essentially intentional, purporting to represent properties of things, nevertheless there is scope for different theories of how they evolve to be that way, and the basic notion of the objectification of a response may well remain the central ingredient in any such explanation.

Promising

Promising is often seen as a social practice with specific rules, determining when a promise has been made and requiring that duly made promises be kept. Accordingly, many philosophers have sought to explain the obligation to keep a promise by appealing to a duty to abide by such rules, whether because of the social benefits of the practice or because fairness requires one to abide by it. Others see breaking a promise as a direct wrong to the person whose expectations are disappointed.

Since one can be obliged to keep a promise even when some other course of action would produce greater happiness (or better consequences as measured by some other standard), the obligation to keep a promise cannot be derived simply from the beneficial consequences of doing so (see Consequentialism). In order to explain this obligation, many philosophers have been drawn to the idea that promising is a social practice whose rules, including the rule that promises must in general be kept, we are bound to obey. They have, however, offered different accounts of why we are so bound.

Hume (1739-40) argued that promises depend on the existence of a convention, although his account differed from most modern ones in emphasizing the *virtue* of fidelity rather than a duty or obligation (see Hume, D. §4). Hume called fidelity (or more generally the virtue of justice, of which fidelity is a central component) an 'artificial' virtue because he thought that the moral approval that an instance of fidelity excites derives from the usefulness of the general pattern of which it is a part rather than from the consequences of that particular action (which may in fact lead to more harm than good).

Practice-based accounts of promises have sometimes been seen as a way of reconciling utilitarian and apparently nonutilitarian intuitions (see Utilitarianism). Rawls, for example, argued in 'Two Concepts of Rules' (1955) that (1) promise making, like a move in a game, is an action that presupposes the rules of a certain practice, and (2) while the practice as a whole can be given a utilitarian justification, actions within it can be justified only in ways that its rules specify (see Rawls, J.). This means, in particular, that the fact that breaking a promise would produce more happiness than keeping it does not count as a justification for breaking it. Practice-based accounts typically involve two parts, corresponding to (1) and (2) above: an account of the social practice of promising and an explanation of the moral authority of this practice. The latter component need not, however, be utilitarian, and in *A Theory of Justice* (1971) Rawls himself offers a nonutilitarian account of this kind. The moral component in this account is the 'principle of fairness', which specifies that someone who voluntarily accepts the benefits of a just social practice is bound to do his or her part in turn, as the rules of that practice specify. It follows, assuming that the rules of the practice of promising are just, that those who help themselves to the benefits of this practice by using it to stabilize agreements are obliged to keep the promises they have made (except where those rules recognize justification for doing otherwise).

On this account, promising is taken to be a particular social institution, on a par with other institutions set up to provide and distribute various 'public goods'. All such institutions face the threat of 'free riding' by people who would like to get the benefits without bearing their share of the costs, and Rawls' appeal to the 'principle of fairness' construes breaking a promise as an instance of the more general wrong of 'free riding' in this way (see Decision and game theory).

But it is not obvious that the wrongs involved in breaking a promise, or making a deceitful promise, are of this general type. They seem more clearly to be wrongs *to* the person to whom the promise is made rather than to all those who contribute to keeping the institution going. Nor is it clear that promising is a social practice of this kind - one that, like a recycling scheme, is aimed at a certain social purpose, defined by certain (somewhat arbitrary) rules, and exists just in so far as the members of a certain group accept these rules as normative. When we try to decide, in a difficult case, whether someone has good reason for failing to fulfil a promise, it does not seem that we are addressing our minds to a kind of social fact, about what the rules of some particular practice are. Moreover, it seems that making a deceitful promise, or failing, without good reason, to keep a promise sincerely made, are wrongs of a kind that can also be committed in other ways without reference to promises or to any other 'practice'. There are many other ways to induce people to rely on us, thereby making it wrong to disappoint them.

This suggests that the wrongs involved in breaking a promise, or in making a deceitful one, belong to a broader class of wrongs having to do with our responsibility for the expectations we create. Practices of agreement-making, where they exist, are one mechanism for creating such expectations, but not the only one. A number of writers have offered ‘expectation-based’ accounts of promising along these lines. Difficulties faced by such accounts include the problem of explaining how promises can create expectations to begin with without appealing to a notion of obligation that does not arise from expectation, and the problem of explaining how promises can be binding in cases in which no expectation is in fact created (because, for example, the ‘promise’ that is offered is not believed).

There are obvious similarities between the idea of a promise and that of a legal contract, but there are also important differences. The law of contracts attempts to specify exactly the conditions that must be fulfilled in order for a valid contract to be made. As noted above, however, it is not clear that the morality of promises involves an informal institution with definite rules of this kind. The law of contracts, which deals chiefly with commercial transactions, is concerned primarily with questions of whether compensation is owed and how much, rather than with the obligation to specific performance. In the case of promises, however, our concern is almost wholly with the obligation to perform rather than with determining compensation.

Proof theory

Proof theory is a branch of mathematical logic founded by David Hilbert around 1920 to pursue Hilbert's programme. The problems addressed by the programme had already been formulated, in some sense, at the turn of the century, for example, in Hilbert's famous address to the First International Congress of Mathematicians in Paris. They were closely connected to the set-theoretic foundations for analysis investigated by Cantor and Dedekind - in particular, to difficulties with the unrestricted notion of system or set; they were also related to the philosophical conflict with Kronecker on the very nature of mathematics. At that time, the central issue for Hilbert was the 'consistency of sets' in Cantor's sense. Hilbert suggested that the existence of consistent sets, for example, the set of real numbers, could be secured by proving the consistency of a suitable, characterizing axiom system, but indicated only vaguely how to give such proofs model-theoretically. Four years later, Hilbert departed radically from these indications and proposed a novel way of attacking the consistency problem for theories. This approach required, first of all, a strict formalization of mathematics together with logic; then, the syntactic configurations of the joint formalism would be considered as mathematical objects; finally, mathematical arguments would be used to show that contradictory formulas cannot be derived by the logical rules.

This two-pronged approach of developing substantial parts of mathematics in formal theories (set theory, second-order arithmetic, finite type theory and still others) and of proving their consistency (or the consistency of significant sub-theories) was sharpened in lectures beginning in 1917 and then pursued systematically in the 1920s by Hilbert and a group of collaborators including Paul Bernays, Wilhelm Ackermann and John von Neumann. In particular, the formalizability of analysis in a second-order theory was verified by Hilbert in those very early lectures. So it was possible to focus on the second prong, namely to establish the consistency of 'arithmetic' (second-order number theory and set theory) by elementary mathematical, 'finitist' means. This part of the task proved to be much more recalcitrant than expected, and only limited results were obtained. That the limitation was inevitable was explained in 1931 by Gödel's theorems; indeed, they refuted the attempt to establish consistency on a finitist basis - as soon as it was realized that finitist considerations could be carried out in a small fragment of first-order arithmetic. This led to the formulation of a general reductive programme.

Gentzen and Gödel made the first contributions to this programme by establishing the consistency of classical first-order arithmetic - Peano arithmetic (PA) - relative to intuitionistic arithmetic - Heyting arithmetic. In 1936 Gentzen proved the consistency of PA relative to a quantifier-free theory of arithmetic that included transfinite recursion up to the first epsilon number, ε_0*; in his 1941 Yale lectures, Gödel proved the consistency of the same theory relative to a theory of computable functionals of finite type. These two fundamental theorems turned out to be most important for subsequent proof-theoretic work. Currently it is known how to analyse, in Gentzen's style, strong subsystems of second-order arithmetic and set theory. The first prong of proof-theoretic investigations, the actual formal development of parts of mathematics, has also been pursued - with a surprising result: the bulk of classical analysis can be developed in theories that are conservative over (fragments of) first-order arithmetic.*

1 Metamathematics

Proof theory is a branch of mathematical logic founded by David Hilbert around 1920 to pursue his programme in the foundations of arithmetic (see Hilbert's programme and formalism). Consistency is the crucial logical notion connected with Hilbert's investigations. In traditional, Aristotelian logic it was viewed as a semantic notion: two or more statements are consistent if they are simultaneously true under some interpretation. In modern logic there is a syntactic definition that fits complex theories since Frege's *Begriffsschrift* (1879): a set of statements is consistent with respect to a logical calculus if no statement of the form $P \& \neg P$ is derivable from the statements by rules of the calculus. If these definitions are equivalent for a logic we have a significant fact, as the equivalence amounts to the completeness (and soundness) of the logic's system of rules. The first such completeness theorem was obtained for sentential logic by Paul Bernays (1918) and, independently, by Emil Post (1921); the completeness of predicate logic was proved by Kurt Gödel in 1930. The crucial step in such proofs shows that *syntactic* consistency implies *semantic* consistency. The converse is established quite directly, but involves the notion of truth. Here we have located one central issue that has motivated proof-theoretic investigations: namely, to avoid the uncritical use of the broad concept of classical truth for infinite mathematical structures.

Cantor applied consistency in an informal way to sets. He distinguished, for example in a letter to Dedekind, a consistent from an inconsistent multiplicity: the latter is such ‘that the assumption that all of its elements ‘‘are together’’ leads to a contradiction’, whereas the elements of the former ‘can be thought of without contradiction as ‘‘being together’’’. Cantor had also conveyed these distinctions by letter to Hilbert in 1897. (See Purkert and Ilgauds (1987) for the text of the letters and Sieg (1990) for the wider historical context.) Hilbert pointed out, both implicitly (1900) and explicitly (1905), that Cantor had not given a rigorous criterion for distinguishing between consistent and inconsistent multiplicities. Hilbert suggested remedying the problem for analysis and giving the proof of the ‘existence of the totality of real numbers or - in the terminology of G. Cantor - the proof of the fact that the system of real numbers is a consistent (complete) set’ by establishing the consistency of an axiomatic characterization of the real numbers (1900). Indeed, he claimed that consistency could be established ‘by a suitable modification of familiar methods’. Hilbert’s own hints, partly in unpublished lecture notes, together with remarks by Bernays, make it plausible that he had a model-theoretic proof in mind. This problematic can be traced back to considerations in Dedekind’s work (1888) as explicated carefully in his letter to Keferstein, where he asked of his notion ‘simply infinite system’, ‘does such a system *exist* at all in the realms of our ideas? Without a logical proof of existence it would always remain doubtful whether the notion of such a system might not perhaps contain internal contradictions’. Clearly, Dedekind tried to establish consistency by exhibiting a suitable ‘logical’, that is, set-theoretic, model.

In 1904 Hilbert began to pursue a completely different strategy for giving consistency proofs. His new way of proceeding was still aimed at securing the existence of sets, but intended to exploit the formalizability of the theory at hand. Formalizations had to satisfy requirements stricter than those imposed on the structure of theories by the traditional (Euclidean) axiomatic-deductive method. The additional requirement was the regimentation of inferential steps in proofs: not only did axioms have to be given in advance, but the rules representing steps in mathematical arguments had to be taken from a predetermined list. To avoid a regression in the definition of proof and to achieve intersubjectivity at an absolutely minimal level, the rules had to be ‘formal’ or ‘mechanical’ and had to depend only on the syntactic form of statements. Thus, to exclude any ambiguity, a precise and effectively described language was also needed to formalize particular theories; the indications (Hilbert 1905) were very sketchy, however.

The general kind of requirements had been clear to Aristotle and were explicitly formulated by Leibniz; but only Frege, in his *Begriffsschrift*, presented - in addition to an expressively rich language with relations and quantifiers - an adequate logical calculus. Through the formalization of mathematical proofs Frege pursued a clear philosophical aim, namely to recognize the ‘epistemological nature’ of theorems. In the introduction to his *Grundgesetze der Arithmetik* (see Frege, G.), he wrote: ‘By insisting that the chains of inference do not have any gaps we succeed in bringing to light every axiom, assumption, hypothesis or whatever else you want to call it on which a proof rests; in this way we obtain a basis for judging the epistemological nature of the theorem.’ An epistemological analysis of theorems was also aimed for by Hilbert in his work on the foundations of geometry, but done quite differently, relying on a more traditional axiomatic presentation and pushing forward genuinely metamathematical investigations. For the emerging proof-theoretic work the formal aspect Frege had emphasized would be exploited by Hilbert in a distinctively novel way.

Hilbert repeatedly gave courses on the foundations of mathematics in the period 1904 to 1917; the spirit of these lectures is captured in his Zurich talk ‘Axiomatisches Denken’ (1918). The mathematical development and philosophical clarification of a new consistency programme began to be given only in Hilbert’s lectures on *Prinzipien der Mathematik* (Principles of Mathematics) presented in the winter term of 1917/1918. These lectures mark the beginning of the fruitful collaboration with Bernays, who supported Hilbert’s preparation in essential ways and also wrote careful notes. The notes of these and later lectures are amazing documents, as one finds in them for the first time a detailed modern presentation of the syntax and informal semantics of predicate logic and of finite type theories. The 1917/1918 notes served as the basis for Hilbert and Ackermann’s *Grundzüge der theoretischen Logik* (1928); indeed, with minor exceptions the notes contain all the material presented in the book. In lectures during the summer term of 1920 and the winter term of 1921/1922, proof theory and the ‘finitist consistency programme’ emerged.

2 Hilbert’s programme

For the purpose of the consistency programme, metamathematics was taken in Hilbert’s 1921/1922 lectures to be included in, if not coextensive with, the part of mathematics acceptable to constructivists such as Kronecker and Brouwer. The point of consistency proofs was no longer to guarantee the existence of sets, but to establish the instrumental usefulness of classical mathematical theories *T* - say, set theory - with respect to finitist mathematics. That focus rested on the observation that the statement formulating the consistency of *T* is equivalent to the reflection principle

$$Pr(a, `\sigma') \Rightarrow \sigma.$$

Here, *Pr* is the finitist proof predicate for *T*, σ a finitistically meaningful statement, and ‘σ’ its translation into the language of *T*. A finitist consistency proof for *T* would thus ensure that *T* is a reliable instrument for the proof of finitist statements. Other important metamathematical issues were the completeness and decidability of theories.

The formalizability of mathematics was obviously crucial for this proof-theoretic approach, and the programmatic goal was seen as a way to circumvent some philosophical issues, for example, concerning the nature of infinite sets in the case of set theory. For these reasons Hilbert’s philosophical position is (still) frequently equated with formalism in the sense of Frege’s articles ‘Über die Grundlagen der Geometrie’ (1903, 1906; see Frege, G.) and of Brouwer’s inaugural address ‘Intuitionism and Formalism’ (1913). Such a view is not completely unsupported by some of Hilbert’s polemical remarks during the 1920s, but on balance his philosophical views developed into a sophisticated instrumentalism, if that label is taken in Ernest Nagel’s judicious sense (see Nagel 1961). Hilbert’s is an instrumentalism emphasizing the contentual motivation of mathematical theories; that is perhaps most clearly expressed in the first chapter of Hilbert and Bernays (1934). A sustained philosophical analysis of proof-theoretic research in the context of broader issues in the philosophy of mathematics was provided by Bernays; his penetrating essays stretch over five decades (see Bernays 1976). Feferman (1988) and Sieg (1988) give complementary accounts; for altogether contrasting approaches, see Detlefsen (1986) and Simpson (1988).

The mathematical work is most remarkable for what it started, as it constitutes the beginnings of modern mathematical logic. Even before the work of Gödel and Gentzen it was rich in accomplishments: consider, as examples, Bernays’ completeness proof for sentential logic; the partial solutions to the decision problem (Hilbert’s *Entscheidungsproblem*) for predicate logic obtained by Behmann, Bernays, Schönfinkel and Herbrand; and the consistency proofs given by Ackermann, von Neumann and Herbrand. Taking for granted the broader conceptual clarifications and the focus on first-order logic, Herbrand’s ‘*théorème fondamentale*’ is perhaps the most significant result on purely logical grounds, but also because of its applicability in consistency proofs. Gödel pointed to its essence when he gave in a 1933 lecture the following formulation of Herbrand’s theorem: ‘If we take a theory which is constructive in the sense that each existence assertion made in the axioms is covered by a construction, and if we add to this theory the non-constructive notion of existence and all the logical rules concerning it, for example, the law of excluded middle, we shall never get into any contradiction’ (see Herbrand’s theorem).

The results obtained in the 1920s, including Herbrand’s theorem, were disappointing when measured against the hopes and ambitions of the Hilbert school: Ackermann, von Neumann and Herbrand had established essentially the consistency of first-order arithmetic with a very restricted principle of induction (for quantifier-free formulas). Actual limits on finitist considerations for consistency proofs had been reached; that became clear in 1931 through Gödel’s theorems and the realization that finitist proofs could be formalized in a weak fragment of number theory (see Gödel’s theorems). Initially, Gödel did not share the view on the limits of finitist reasoning, as is clear from the final remarks in his ‘Über formal unentscheidbare Sätze der *Principia Mathematica* und verwandter Systeme I’ (On Formally Undecidable Propositions of *Principia Mathematica* and Related Systems) (1931) and contemporaneous correspondence with von Neumann and Herbrand. But by December 1933, when he lectured in Cambridge, Massachusetts, he had changed his position: having isolated a ‘system A’ - essentially a version of primitive recursive arithmetic (PRA) - he made the following claim: ‘Now all the intuitionistic [that is, finitist] proofs complying with the requirements of the system A which have ever been constructed can easily be expressed in the system of classical analysis and even in the system of classical arithmetic, and there are reasons for believing that this will hold for any proof which one will ever be able to construct.’

The solvability of the *Entscheidungsproblem* had been made implausible by Gödel’s results, but the actual proof of unsolvability had to wait until 1936 for a conceptual clarification of ‘mechanical procedure’ or ‘algorithm’. Such a

clarification was achieved mainly through the work of Church and Turing (see Church's thesis; Computability theory). A precise notion of mechanical procedure was also needed to prove the incompleteness theorems for *general* 'formal' theories satisfying basic representability and derivability conditions; after all, Gödel had established limits only for (formalizations of) particular theories, such as the system of *Principia Mathematica* and then current axiomatic set theories. In his attempt to characterize a proper extension of the class of primitive recursive functions, Gödel introduced (in his Princeton lectures of 1934) the general recursive functions through an equational calculus (see Computability theory §2). The informal concept underlying Gödel's and also Church's approach - calculability of functions in a 'formal' calculus - was carefully analysed by Hilbert and Bernays (1939: supplement 2); they formulated recursiveness conditions for general deductive formalisms and showed that the number-theoretic functions whose values can be calculated in formalisms satisfying these conditions are exactly the general recursive ones.

The impact of the incompleteness theorems on Hilbert's programme was profound and yet limited. On the one hand, as remarked above, they pointed out definite limits of finitist considerations; on the other hand, they left open the possibility of modifying the programme to a *general reductive programme* that was no longer aiming for 'absolute' finitist consistency proofs, but rather for consistency proofs relative to 'appropriate' constructive theories. Before Gödel's results were known, Bernays (1930) had given a detailed and searching analysis of the philosophical aims of Hilbert's proof theory; in the *Postscriptum* published in 1976, Bernays expressed clearly what was lost due to the incompleteness theorems: the sharp distinction between what is intuitive and what is non-intuitive, a distinction that was basic for the proposed philosophical treatment of the problem of the infinite. Thus, it is this particular 'solution' to a philosophical problem that was shown to be impossible.

Work in proof theory continued with the explicit goal of achieving relative consistency proofs. Such work is in a venerable mathematical tradition, as the many examples of significant results show: for example, the consistency of non-Euclidean relative to Euclidean geometry; that of Euclidean geometry relative to analysis; the consistency of set theory with the axiom of choice relative to set theory without it; that of set theory with the negation of the axiom of choice relative to set theory. The mathematical significance of relative consistency proofs is often brought out by sharpening them to conservative extension results. Such results may ensure, for example, that the theories have the same class of provably total functions (see §6). However, the initial motivation for such arguments is most frequently philosophical: one wants to guarantee the coherence of the original theory on an epistemologically distinguished basis. One has to see the specific results that have been obtained in the pursuit of the general reductive programme from this perspective.

3 Mathematical work

The development of the general reductive programme is characterized by modifications of the two-pronged approach of Hilbert's original programme, namely (1) weakening the theories in which parts of mathematics are formalized, and (2) strengthening the theories in which the metamathematical considerations are carried out and, consequently, relative to which constructive consistency proofs can be given. The first modification reaches back to Weyl's *Das Kontinuum* (1918) and culminated in the 1970s, when it was realized that the classical results of mathematical analysis can be obtained in conservative extensions of first-order arithmetic. The second modification started with the work of Gödel and Gentzen in 1933, when they established independently the consistency of classical arithmetic relative to intuitionistic arithmetic; it led in the 1970s and 1980s to consistency proofs of subsystems of second-order arithmetic or, synonymously, subsystems of analysis relative to intuitionistic theories of constructive ordinals. Obviously, only a sketch of some main results can be attempted here.

Second-order arithmetic has been used for some time as a framework for the formal development of classical mathematical analysis; that is, the theory of the continuum set-theoretically described by Dedekind and Cantor. Because of this mathematical adequacy, second-order arithmetic and a variety of subsystems have been thoroughly investigated. The main set-theoretic principles for these systems are the comprehension axiom (CA)

$$(\exists X)(\forall y)(y \in X \Leftrightarrow S(y))$$

and the axiom of choice (AC) in the form

$$(\forall x)(\exists Y)S(x,Y) \Rightarrow (\exists Z)(\forall x)S(x,Z_x),$$

where *S* is in each case an arbitrary formula of the language and thus may contain set quantifiers; $y \in Z_x$ is defined to mean $\langle y, x \rangle \in Z$. These principles are impredicative, as the sets *X* and *Z* whose existence is postulated are in general characterized by reference to all sets of natural numbers. The induction principle is formulated either as a schema or as a second-order axiom

$$(\forall X)(0 \in X \;\&\; (\forall y)(y \in X \Rightarrow y' \in X) \\ \Rightarrow (\forall x) x \in X).$$

Theories are denoted by the name of their set-existence principle enclosed in parentheses; thus (CA) names full analysis. If $\restriction$ follows its name, a theory uses the second-order axiom to formalize induction. Two general results are of interest, as they show that second-order arithmetic has a certain robustness: (CA) is proof-theoretically equivalent to Zermelo-Fraenkel set theory without the power-set axiom; (AC) is conservative over (CA) for Π^1_4-formulas and properly stronger, as there is a Π^1_2-instance of AC not provable in (CA). In the presence of full CA, the theories with the induction schema, respectively, the second-order axiom of induction are equivalent, but they can be of strikingly different strength, when the set-existence principles are restricted; for example, $(\Pi^0_\infty\text{-CA})\restriction$ is conservative over Peano arithmetic (PA), whereas $(\Pi^0_\infty\text{-CA})$ proves the consistency of PA.

In 1917/1918 Hilbert and Bernays used ramified type theory with the axiom of reducibility to develop analysis; the published presentation (1939: supplement 4) is based on this early work, but employs full second-order arithmetic as the formal framework. They encouraged developments with restricted means already in 1920, writing of Brouwer and Weyl:

> The positive and fruitful part of the investigations into the foundations of mathematics carried out by these two researchers fits into the mould of the axiomatic method and is exactly in the spirit of this method. For one investigates here, how a part of analysis can be delimited by a certain narrower system of assumptions.
>
> (Hilbert and Bernays 1920: 34)

Subsystems of analysis are now mainly defined by restricting *S* in the set-existence schemata to particular classes of formulas. The set-theoretic demands can be reduced dramatically: Hilbert and Bernays' presentation (1939), for example, can be given quite readily in $(\Pi^1_1\text{-CA})\restriction$. Strictly mathematical work continued to accompany work on consistency proofs for subsystems; it had the aim of establishing the mathematical significance of subsystems and made use of work in the constructivist tradition.

By the mid-1970s, through final efforts of Feferman, Friedman and Takeuti, it was clear that classical analysis could be carried out in conservative extensions of number theory, for example, $(\Pi^0_\infty\text{-CA})\restriction$. In this context Friedman suggested pursuing a strategy familiar from investigations of the axiom of choice in set theory; namely, to establish the equivalence of certain set-existence principles with mathematical theorems. This theme is played with surprising variations in Friedman's and Simpson's work on subsystems and gave rise to the enterprise of 'reverse mathematics'. To mention just two, by now classic, examples: CA for arithmetic formulas is equivalent to the theorem that every bounded sequence of reals has a least upper bound and to König's lemma. Friedman introduced a second-order theory WKL_0 that extends primitive recursive arithmetic conservatively for Π^0_2-formulas; the theory is weak, but still provides a very good basis for developing parts of analysis and algebra. Simpson (1988) not only considers the development of mathematics in such a conservative extension of PRA a 'reductionist programme', but equates it with Hilbert's programme. One should recall, however, that Hilbert did not propose to redo all of mathematics in (a conservative extension of) PRA, but rather to justify - via finitist consistency proofs - the use of strong classical theories sufficient for the direct formalization of mathematical practice.

4 Logical tools

Hilbert's central idea for the metamathematical treatment of the consistency problem found its expression in what is known as the ε-calculus and the associated substitution method. Hilbert and Bernays (1939) present what was achieved in its terms; even Herbrand's (difficult) work was recast in terms of the ε-calculus. This tradition was kept up by Tait (1965) and more recently by Mints (1994). However, other logical tools turned out to be more useful for proof-theoretic investigations: Gentzen's sequent calculi (see Natural deduction, tableau and sequent systems §2) and Gödel's so-called *Dialectica* interpretation. In the latter, Gödel used computable functionals of

finite type to obtain a reduction of intuitionistic arithmetic (HA); joining this reduction with the consistency of PA relative to HA, a consistency proof relative to the system of these functionals was obtained. Influenced by the considerations of Hilbert (1926), Gödel presented this work in a lecture at Yale in 1941, but published it only in 1958 (see Gödel's theorems). Spector (1962) gave a consistency proof for full classical analysis using bar recursive functionals of finite type; this proof prompted a searching analysis in the *Stanford Report on the Foundations of Analysis* (1963).

Here the focus is on sequent calculi, as they have found the most extensive use and widest applicability. In the form given to them by Tait (1968), they allow the proof of finite sets of formulas built up from literals (atomic formulas or negations of such), conjunction, disjunction, universal and existential quantification and - depending on the theory - infinitary conjunction and disjunction. Thus, for just first-order logic the basic logical symbols are '$\wedge$', '$\vee$', '$\exists$', '$\forall$' and the rules of the calculi include the following ones, where Γ is used as a syntactic variable ranging over finite sets of formulas, Γ, ϕ stands for the union of Γ and the singleton ϕ, and $a \in P(\Gamma)$ means that the parameter *a* occurs in one of the formulas in Γ:

LA: $\quad \Gamma, \varphi, \neg\varphi, \quad \varphi$ atomic

$\wedge$: $$\frac{\Gamma, \varphi_0 \quad \Gamma, \varphi_1}{\Gamma, \varphi_0 \wedge \varphi_1}$$

$\vee_i$: $$\frac{\Gamma, \varphi_i}{\Gamma, \varphi_0 \vee \varphi_1}, \quad i = 0, 1$$

C: $$\frac{\Gamma, \varphi \quad \Gamma, \neg\varphi}{\Gamma}$$

$\forall$: $$\frac{\Gamma, \varphi a}{\Gamma, (\forall x)\varphi x} \quad a \notin P(\Gamma)$$

$\exists$: $$\frac{\Gamma, \varphi t}{\Gamma, (\exists x)\varphi x}$$

The crucial claim established by Gentzen was his '*Hauptsatz*' or cut-elimination theorem: every derivation in the logical system using the cut rule *C* can be transformed into a cut-free or normal derivation. Inspecting the rules, one notices that the premises of all the rules (except for *C*) contain only subformulas of formulas in the conclusion. Consequently, a normal derivation of a sequent Γ contains only subformulas of elements in Γ. This is the crucial subformula property of normal derivations, providing a bound on the complexity of formulas that can occur in a proof of Γ. In Gentzen (1935) this metamathematical fact is established and used to obtain in a most perspicuous way the most far-reaching consistency result that had then been obtained, namely Herbrand's.

For full first-order number theory PA this treatment was extended by Gentzen (1936) to a partial cut-elimination argument whose termination was established by quantifier-free transfinite induction up to the first epsilon number - $\mathrm{TI}(\varepsilon_0)$. Gentzen showed (1943) that this induction schema for every ordinal α less than ε_0 can be established in PA; this is the first 'ordinal analysis' of a formal theory. In the 1950s Lorenzen and, much more extensively, Schütte used infinitary extensions of Gentzen's finitary systems; in particular for the treatment of PA they used the so-called ω-rule that allows one to infer $\Gamma, (\forall x)\phi x$ from the premises $\Gamma, \phi n$ for each natural number *n* (see Non-constructive rules of inference §1). Though derivations are now infinite, PA-derivations can be embedded into finitistically described ones and can be transformed effectively into cut-free derivations; the natural ordinal length of these derivations is bounded by ε_0. Schütte extended these methods to treat systems of ramified analysis RA_α (of order α) and obtained, in particular, ordinal bounds on the length of normal derivations in terms of the Veblen hierarchy of ordinal functions. This work was used in 1963 by Feferman and Schütte independently to characterize the ordinal Γ_0 of predicative analysis, that is, the first ordinal α such that $\mathrm{TI}(\alpha)$ cannot be proved in RA_β for β less than α.

5 Reductive results

The mathematical work described in §3 was to a large extent inspired by the attempt to establish the significance of relative consistency proofs and/or to focus on manageable subsystems that might be a proper next target for such proofs. Most of the reductive results mentioned below can be established by the metamathematical tool of the sequent calculi, though some of the original proofs used different techniques.

The Gödel-Gentzen result for number theory can be extended to ramified analysis and also to obtain conservativeness for Π^0_2-formulas. This provides a relative consistency proof, as ramified systems with intuitionistic logic are certainly acceptable constructively (as long as the ordinals along which the systems are iterated are acceptable). In the early 1960s, partly through the study of predicativity, significant subsystems with *S* restricted to small classes of analytic formulas were isolated, among them $(\Sigma^1_1\text{-AC})$ and $(\Delta^1_1\text{-CA})$. Kreisel pointed out that

$(\Sigma^1_1\text{-AC}) \supseteq (\Delta^1_1\text{-CA})$.

Friedman showed that $(\Sigma^1_1\text{-AC})$ is conservative over $(\Delta^1_1\text{-CA})$ for Π^1_2-formulas; that the inclusion is proper was established later by Steel. Indeed, $(\Sigma^1_1\text{-AC})$ is conservative for Π^1_2-formulas over $(\Pi^1_0\text{-CA})_{<\varepsilon_0}$, a theory based on the transfinite iteration of the jump-operator and equivalent to ramified analysis of level less than ε_0. This result, due to Friedman, allowed the determination of the proof-theoretic ordinal of the systems, but it also showed - and this was quite unexpected - that these prima facie impredicative theories were predicative in the sense of Feferman and Schütte. Feferman (1964) and Kreisel (1968) provide excellent summaries.

Friedman's theorem for $(\Sigma^1_1\text{-AC})$ turned out to be a special case of a general result: $(\Sigma^1_{n+1}\text{-AC})$ is conservative over $(\Pi^1_n\text{-CA})_{<\varepsilon_0}$ for formulas in F_n, where F_0 is Π^1_2, F_1 is Π^1_3, and F_n is Π^1_4 for $n > 1$ (see Friedman 1970). As just explained, the case $n = 0$ was of special interest for the study of predicativity; the case $n = 1$ is also to be placed in the context of foundational investigations. The most immediate context is provided by Feferman (1970), who relates the systems $(\Pi^1_1\text{-CA})_{<\varepsilon_0}$ to the classical theory for (less than ε_0 times iterated) classes defined by generalized inductive definitions. Well-known examples are the classes O of constructive ordinals and W of recursive well-founded trees. Between them, Friedman and Feferman reduced the subsystems $(\Sigma^1_2\text{-AC})$ and $(\Delta^1_2\text{-CA})$ to the classical theory of the tree classes $\mathbf{W}_\nu$ with index ν less than ε_0. Feferman (1977) gives a detailed survey of mathematical and proof-theoretic work, including these last results.

Kreisel had introduced intuitionistic theories of iterated inductive definitions in the *Stanford Report* (1963); these theories were viewed as codifying constructive principles that might be used in consistency proofs for subsystems of analysis. Feferman's and Friedman's work described above established connections between subsystems of analysis and classical theories of inductive definitions, making a crucial step towards answering the major problem posed by Kreisel (1968): reduce $(\Sigma^1_2\text{-AC})$ to a constructive theory of inductive definitions. That would provide, as Kreisel put it, 'a solution to Hilbert's problem for the subsystem of analysis… $(\Sigma^1_2\text{-AC})$'. The classical theories for classes defined by generalized inductive definitions are reducible to intuitionistic theories for accessible such classes. This allowed, in particular, a satisfactory solution of Kreisel's open problem, as $(\Sigma^1_2\text{-AC})$ was shown to be reducible to $(\mathrm{ID})_{<\varepsilon_0}(\mathbf{O})$, the intuitionistic theory of constructive number classes with index less than ε_0. These and many further results were obtained by Buchholz *et al*. (1981); in particular, the ordinal analysis of the subsystems at hand. This work was influenced by earlier considerations of Howard, Tait and Takeuti.

Subsystems of set theory, in particular of admissible set theory, were used by Jäger and Pohlers in the early 1980s to provide a unifying approach to the investigations and, it was hoped, an avenue for analysing even stronger systems than those corresponding to the subsystems mentioned above (see Jäger 1986). This has indeed been a successful strategy and reveals, in the work of Rathjen and others, a deep connection between large cardinals and the constructive ordinals needed for the proof-theoretic investigation of such systems. Rathjen (1995) succeeded in analysing $(\Pi^1_2\text{-CA})$; it seems that the techniques developed for this case might allow the treatment of full analysis. These proof-theoretic investigations can no longer be motivated by the concern of 'securing' mathematical practice: the systems that are investigated are much stronger than needed for practice; the constructive ordinals used in the metamathematical theory are obtained in analogy to large cardinals in set theory.

The systems WKL_0, $(\Pi^0_\infty\text{-CA})\restriction$ and $(\Pi^1_1\text{-CA})\restriction$ have been recognized as significant for the formalization of

mathematical practice and are reducible to theories based on principles that are acceptable from constructive positions; after all, they are conservative for Π^0_2-formulas over PRA, HA and the intuitionistic theory for the finite constructive number classes $(\mathrm{ID})_{<\omega}(\mathbf{O})$. This provides a coherent perspective bringing out the complementary character of mathematical and metamathematical work that ultimately aims at relating significant parts of mathematical practice to distinctive foundational positions. But there is no obvious answer to the question 'What is the mathematical significance of those subsystems, when taken as vehicles for the formal axiomatic study of ordinary mathematics?'; similarly there is no obvious answer to the question 'What is the philosophical significance of the corresponding systems PRA, HA and $(\mathrm{ID})_{<\omega}(\mathbf{O})$, when taken as formal expressions of foundational positions?'. There is ample room for reflection on these questions; the work reported here and in the literature provides rich and crucial data (see Sieg 1990). For the philosophical reflection on the foundations of mathematics the investigations of subsystems of set theory provide additional, significant material: what are constructions that lead to 'accessible domains' and how is it that we recognize their associated laws?

6 Outlook

'Internal' mathematical and philosophical challenges of work in proof theory were sketched at the end of the previous section. However, the foundational goals of proof-theoretic investigations have been complemented over the last few decades by other important initiatives.

First, in the 1950s, Kreisel initiated work that was to exploit the gap between provability in particular formal theories and truth. That led, on the one hand, to 'global' characterizations of the provably total functions of theories and to related independence results. On the other hand, by attending 'locally' to mathematical details of proofs and by using proof-theoretic techniques, it led to explicit computational information of mathematical significance. This seems to have come to fruition through work by Luckhardt (1989) and Kohlenbach (1995).

Second, methods and results of mathematical logic, but in particular of proof theory, have played an increasing role in computer science. Clearly, there has also been significant and stimulating influence in the other direction. Various (type) systems - for example, Martin-Löf's, Girard's system F, and Feferman's systems of explicit mathematics - have been used for the presentation of proofs and computations, but also for describing transformations on them.

Third, there is a direct connection to the general topic of theorem proving; investigations here, when focusing on automated proof search, might reflect back into proof theory by providing data for a 'structural theory of (mathematical) proofs'. Such a structural proof theory would go beyond the representation of proofs in formal theories and articulate search heuristics expressing leading mathematical ideas for particular parts of mathematics. Saunders Mac Lane suggested such an extension of proof-theoretic investigations in his Göttingen dissertation of 1934, but it has been pursued only recently through computer implementation of appropriate search procedures.

Proper names

The Roman general Julius Caesar was assassinated on 14 March 44 BC by conspirators led by Brutus and Cassius. It is a remarkable fact that, in so informing or reminding the reader, the proper names 'Julius Caesar', 'Brutus' and 'Cassius' are used to refer to three people each of whom has been dead for about two thousand years. Our eyes could not be used to see any of them, nor our voices to talk to them, yet we can refer to them with our words.

The central philosophical issue about proper names is how this sort of thing is possible: what exactly is the mechanism by which the user of a name succeeds in referring with the name to its bearer? As the example indicates, whatever the mechanism is, it must be something that can relate the use of a name to its bearer even after the bearer has ceased to exist.

*In modern philosophy of language there are two main views about the nature of the mechanism. On one account, which originated with Frege, a use of a name expresses a conception or way of thinking of an object, and the name refers to whatever object fits, or best fits, that conception or way of thinking. Thus with 'Cassius', for example, I may associate the conception 'the conspirator whom Caesar suspected because of his size' (recalling a famous speech in Shakespeare's Julius Caesar). Conception theories are usually called 'sense' theories, after Frege's term '*Sinn*'. The other account is the 'historical chain' theory, due to Kripke and Geach. In Geach's words, 'for the use of a word as a proper name there must in the first instance e someone acquainted with the object named…. But…the use of a given name for a given object…can be handed on from one generation to another…Plato knew Socrates, and Aristotle knew Plato, and Theophrastus knew Aristotle, and so on in apostolic succession down to our own times. That is why we can legitimately use "Socrates" as a name the way we do' (1969-70: 288-9).*

1 Sense theories: Introduction

The idea that names express reference-determining conceptions or 'senses' originated with Frege (1892). But Frege was led to it not by wondering about the mechanism of reference, but rather about the difference in 'cognitive value' between two true identity statements of the respective forms $a = a$ and $a = b$ (for example, 'Clark Kent is Clark Kent' and 'Clark Kent is Superman'). Statements of the former sort, he says, are a priori, while the latter 'often contain very valuable extensions of our knowledge and cannot always be established a priori' ([1892] 1980: 56). Frege takes this to show that the propositions expressed by $a = a$ and $a = b$ cannot be the same even when *a* and *b* are names of the same person. Yet if the names do corefer, there is no difference in the references of the constituents of $a = a$ and $a = b$; moreover, these two sentences are assembled in the same way. So either they cannot express different propositions, or else - and this is the inference Frege drew - what determines the proposition a sentence *S* expresses cannot just have to do with the structure of *S* and the *references* of its constituent words and phrases (see Frege, G. §§3-4; Sense and reference §1).

Frege's proposal was that in addition to possessing a reference, any meaningful expression has a sense, the sense being a 'way of thinking' of the reference. The proposition a sentence expresses is determined by the senses of the words in it, not their references. Thus 'Clark Kent is Clark Kent' and 'Clark Kent is Superman' express different propositions because 'Clark Kent' and 'Superman' express different senses, senses which happen to be ways of thinking of the same reference. Taking the Superman fiction to be fact, the sense of 'Clark Kent' might be 'the mild-mannered reporter on *The Daily Planet* who has a crush on Lois Lane' while the sense of 'Superman' might be 'the blue-suited extraterrestrial who flies'. Here we specify different conceptions of the same individual in two definite descriptions (expressions of the form 'the so-and-so' - see Descriptions). The proposition that Superman is Clark Kent therefore has the content that the blue-suited extraterrestrial who flies is the mild-mannered reporter on *The Daily Planet* who has a crush on Lois Lane, which may indeed be, in Frege's phrase, an extension of our knowledge.

It was Frege's view that in an ideal language each name would have a fixed sense and reference for everyone; in an ordinary natural language, there are names that fail to refer, and users may fail to agree on the sense of a name for a specific individual, which Frege thought of as deficiencies of natural language. In a modification of Frege's views, Searle (1958) allowed that a name may be associated with a whole range of descriptions, different users using different ranges; the bearer of the name need not satisfy all the conditions mentioned in the descriptions, only 'a sufficient number', an intentionally vague condition.

Sense theories along such lines as these have been called ‘famous deeds’ sense theories. Famous deeds sense theories appear to have been conclusively refuted by Kripke (1972, 1980). Kripke objects to such sense theories both as they respond to Frege’s own puzzle about the difference between $a = a$ and $a = b$, and as they address our initial question about the mechanism of reference. Let us consider these two issues in turn.

2 Sense theories: Do names express senses?

According to Kripke, the propositions one expresses using names do not involve senses or ways of thinking expressed by the names, otherwise some such propositions would be both metaphysically necessary and a priori, which they are clearly not. For example, suppose the sense of ’Aristotle’ is ‘the pupil of Plato who tutored Alexander’. Then the sentence

(1) Aristotle was a pupil of Plato

would express the proposition with the content

(2) The pupil of Plato who tutored Alexander was a pupil of Plato.

But (2) is, in a certain sense, necessary, while (1) is not. There is no way things could have gone in which (a) a unique pupil of Plato who tutored Alexander exists and (b) that person was not a pupil of Plato. On the other hand, there are many ways things could have gone in which (a′) Aristotle exists but (b′) Aristotle was not a pupil of Plato (for example, he died young). In other words, granted that there is such a person as Aristotle, he may be a pupil of Plato or he may not be. But granted that there is such a person as the pupil of Plato who tutored Alexander, it follows that he is a pupil of Plato.

This example brings out Kripke’s famous distinction between ‘rigid’ and ‘non-rigid’ designators. In thinking about or describing other ways things could have gone (other possible worlds) we use a proper name such as ‘Aristotle’ consistently to denote the same person; this makes proper names rigid designators. But we use definite descriptions such as ‘the pupil of Plato who tutored Alexander’ differently. With respect to the actual world, this description picks out Aristotle; with respect to a possible world where someone else is the one and only pupil of Plato who tutored Alexander, the description picks out that other person, not Aristotle; and with respect to a possible world where either Plato or Alexander does not exist, the description fails to pick out anyone, even if Aristotle does exist. Hence such descriptions are non-rigid designators. Certain descriptions, such as ‘the positive square root of 9’, are as rigid as proper names, but this is on account of their subject matter, not their semantic role. It is because the typical famous deeds description is non-rigid that the contrast between pairs such as (1) and (2) *vis-à-vis* necessity and contingency arises (see Reference §2).

Just as (1) and (2) differ in modal status, they differ epistemically: bracketing the question of existence, (2) is, in a limited sense, knowable a priori, while (1) is not. That is, granted that there was such a person as Aristotle, it is a further, empirical question whether he was a pupil of Plato (there may be a controversy among historians about this). But granted that there was such a person as the pupil of Plato who tutored Alexander, it is not a further question, *a fortiori* not an empirical one, whether he was a pupil of Plato.

The same objections arise to Searle’s modified version of the sense theory. For example, no matter what range of descriptions we associate with a name, they will generate statements that are a priori in the manner of (2). If being ϕ logically implies being ϕ', then

(3) The thing which is *F*-and-*G* or *G*-and-*H* is *F*′ or *G*′ or *H*′

is essentially the same as (2), just more complicated. But if the predicates *F*, *G* and *H* encapsulate famous deeds, the corresponding

(4) *NN* is *F*′ or *G*′ or *H*′,

where ‘*NN*’ is the name with which ‘the thing which is *F* or *G* or *H*’ is associated, will be no more a priori than (1) (Kripke 1980).

3 Sense theories: Do senses determine reference?

Kripke (1972, 1980) demonstrates another flaw in famous deeds sense theories, namely, that they do not provide an adequate answer to the question about the mechanism of reference. This is because (1) the likely candidate for the sense of a name may pick out an object which is not in fact the name's bearer, or may fail to pick out anything, and (2) we can succeed in referring with a name even when we do not have a 'famous deeds' description associated with it.

Kripke illustrates (1) with two examples. If any description is associated with the name 'Gödel' it is 'the discoverer of the incompleteness of arithmetic'. Does this mean that 'Gödel' refers to that person? What if the theorem was actually proved by Schmidt, who died in strange circumstances, and Gödel got hold of Schmidt's work and represented it as his own? The very fact that we can understand this 'what if' shows that the reference of 'Gödel' is not fixed as whoever discovered the incompleteness of arithmetic. And though this example is fictional, there are similar actual cases: Peano's Axioms are not due to Peano; and Einstein was not the inventor of the atomic bomb (Kripke 1980). For a case where there are descriptions that do not pick out any object although the relevant name still refers, Kripke gives the example of the prophet Jonah, who really existed (according to the scholarly consensus), but whose career as described in the Bible is essentially fictitious. Again, the mere intelligibility of the claim 'Jonah was a historical person but everything uniquely identifying that the Bible says about him is fictitious' is enough to show that the reference of 'Jonah' is not fixed as the Hebrew prophet who was swallowed by a whale, or by any other condition, no matter how complicated or disjunctive, derived from the Book of Jonah.

As for (2), successful reference without associated (definite) descriptions, Kripke points out that most people can use the names 'Richard Feynman' and 'Murray Gell-Mann' to refer to those two people, but that, at best, all the typical person knows about either is that he is a famous physicist who won a Nobel Prize (this was before Feynman achieved popular fame for his role in the *Challenger* disaster inquiry). So we have difference in reference with no difference in associated descriptions; therefore associated descriptions are not at the heart of how proper name reference works.

Perhaps these examples only establish such a conclusion for descriptions that encapsulate famous deeds. Kripke considers some other approaches and concludes that they violate an important non-circularity condition: that candidate descriptions must not themselves embed the notion of reference in a way that cannot eventually be eliminated. For example, we might suggest that the reference of 'Socrates' is fixed as 'the man called "Socrates"'. Since 'called' just means 'referred to as', we do not explain how reference to Socrates is possible in this way: what we want to know is how Socrates *gets to be* the man referred to as 'Socrates'. So this goes nowhere as a proposal about the mechanism of reference, and Kripke plausibly argues that the same would be true for more complicated versions of the idea, for example, that 'Gödel' refers to the person to whom the proof of the incompleteness of arithmetic is commonly attributed. So these attempts at a non-famous-deeds description theory fail. However, in view of Kripke's critique of the famous deeds approach, it seems that if any sense theory is to work, it will have to be a non-famous-deeds account of some sort.

4 Historical chains

The main competing account of the mechanism of reference is the Geach-Kripke historical chain account, in which competence to refer with the name is transmitted across generations in the style adverted to in the quotation from Geach in this entry's prologue (1969-70). The historical chain account is sometimes called the 'causal' chain account, since it is held that the links in the chain are forged by transactions of a causal sort. In Kripke's own version, which he says is a 'picture' rather than a theory (1980: 97), a name is introduced into a community by some 'initial baptism' of an object with the name, and then the name is passed on from link to link, it being required at each step that the receiver of the name 'intend…to use it with the same reference as the [person] from whom he heard it' (1980: 96).

If we regard being told about, or otherwise hearing about, an object, as a way of becoming 'acquainted' with it, then the Geach-Kripke account instantiates an approach championed by Russell (1918), who made acquaintance with an object necessary for referring to it. However, Russell's notion of acquaintance was rather idiosyncratic: apart from my own sense-data, my self, universals and perhaps the present moment, I lack acquaintance with things, according to Russell. Since the ordinary names I use, ostensibly for other people and things, are not names of sense-data, Russell claimed that in a 'logical' sense, ordinary names are not 'proper' names. Rather, he

suggested, they are definite descriptions in disguise (see Russell, B.A.W. §9). For this reason, Kripke sometimes calls the view he opposes the 'Frege-Russell theory of names'. The point to bear in mind is that Frege and Russell had different accounts of how reference works (so there is no 'Frege-Russell theory of reference'), but because on Russell's account ordinary names do not really refer, the two philosophers end up saying similar-sounding things about such names.

Returning to Kripke's account of the mechanism of reference in terms of informational exchanges in which the intention to preserve reference is present, the obvious question is whether it is any improvement on circular description theories. After all, the notion of reference enters explicitly into Kripke's necessary condition for successful passing on of the name, and it also enters at the start of the chain, where some kind of demonstrative reference to the object being baptized is standardly made. To put the same question another way, if this account is explanatory, would there be anything wrong with a description theory which attributed to a name '*NN*' and a user of the name *U* the sense 'the object at the start of the chain of reference-preserving links by which I came into mastery of this name', in which 'I' refers to *U*?

One problem with this version of a description theory is that no ordinary speaker of a natural language associates any such description with a proper name, since the description embodies a philosophical theory, and it is difficult to see how one could justify claiming that the association is 'implicit'. Here there is a contrast with Kripke's proposal, which only requires speakers to have the intention to preserve the reference of the new name they have just learned, and it is surely plausible that speakers do have such an intention. Still, there is some sense in which the fundamental nature of the mechanism of reference is left unexplained. For instance, what exactly is it about an actual baptismal service, or about parents announcing their choice of name, that causes a new 'common currency' (see Kaplan 1990) name to be added to the language? Or is the request for further explanation here a demand for a 'reductive' account of reference in terms of non-semantic notions (see Reference §8), something perhaps impossible?

The causal chain picture is not without other difficulties, as Kripke mentions. For instance, straightforward application of the picture could lead to the conclusion that 'Santa Claus' is the name of a certain central European king, which seems wrong. Evans (1973) proposed a different causal account on which the 'causal source' of the information associated with the name determines whom it refers to, though in a possibly complex way. Evans observes that the reference of a name in a linguistic community can change over time if it was originally a name for *x* that was mistakenly but consistently misapplied to *y: y* would ultimately become the bearer of the name, being the dominant causal source of the information associated with it (unless, as Evans notes, younger members of the community defer in their use of the name towards those for whom it was once a name for *x*). Evans subsequently elaborated his account (1982: ch. 11).

5 Direct reference and Frege's puzzle

A striking feature of the Geach-Kripke picture is that it leaves no role for sense to play as that which determines reference. The only candidate for the 'meaning' of a name is therefore the name's reference itself. A theory which claims that the meaning of a name is just its reference, pure and simple, is often called a 'direct reference' theory, 'direct' signifying that reference is not mediated via sense. Such theories trace their origins through Russell back to Mill (1843); more recently, the idea is prominent in the writings of Marcus on reference (1961), and has subsequently been developed and defended in a sustained form by Salmon (1986) and Soames (1994).

The main problem which direct reference theories face is the puzzle about the difference between $a = a$ and $a = b$. The general 'failure of substitutivity' puzzle is the puzzle of how it is possible for the meanings of two sentences to differ if the sentences have the same structure and their corresponding parts have the same meaning. For example,

(5) It is self-evident to any rational thinker that if Superman exists, then Superman = Superman

seems true and 'Superman' and 'Clark Kent' have the same reference. Therefore, according to direct reference theory, (5) should have the same meaning as

(6) It is self-evident to any rational thinker that if Superman exists, then Superman = Clark Kent.

But at first sight, (6) does not even have the same truth-value as (5), never mind the same meaning.

Failure of substitutivity is handled straightforwardly on a sense theory of names which allows that coreferential names can have different senses. The claim would be that (not merely the reference but) the sense of ‘Superman’ enters into the truth-condition of (5), while in (6) the sense of ‘Clark Kent’ is also involved. There are various mechanisms which might be invoked here, Frege’s own being the simplest: in (5) and (6), according to Frege, the proper names refer to their *senses*, rather than to the person they normally refer to (see Propositional attitude statements §1; Sense and reference §5). But the trouble with any explanation of substitutivity failure for proper names that invokes senses is that sense theories of proper names have been so thoroughly battered by Kripke.

Direct reference theory seems to have less to work with to explain the semantic difference between (5) and (6). On perhaps the best known version of the theory, Salmon’s, it is simply denied that there is a semantic difference between (5) and (6). The appearance that substitution changes truth-value in cases such as (5) and (6) is explained as being due to pragmatic effects (see Pragmatics). Apparently, the only alternative for a direct reference theorist is to identify some assumption in the argument that substitution of coreferring names ought not to change meaning and deny that assumption. This strategy produces a possible target. We suggested that what makes substitutivity failure puzzling is that sentences with the same structure whose corresponding parts have the same meaning should themselves have the same meaning. But this presupposes that the meaning of the entire sentence is wholly determined by the meaning of its parts and their manner of composition (see Compositionality). However, the notion of structure alluded to in the phrase ‘manner of composition’ is one which is sensitive only to syntactic categories of expression, not to the identity of expressions. There is another, more ‘logical’ notion of structure, on which use of a different word, even one with the same meaning, can disrupt structure (Putnam 1954). In this logical sense, the structure of ‘if Superman exists, then Superman = Superman’ is ‘if *Et* then *t t*’, while ‘if Superman exists, then Superman = Clark Kent’ has the different structure ‘if *Et* then *t* = *t*Čast;’. If we hold that substitution is acceptable only when it does not change logical structure, then from (5) we can infer merely

(7) It is self-evident to any rational thinker that if Clark Kent exists, then Clark Kent = Clark Kent

which is presumably true if (5) is. Of course, this does not help with cases of substitutivity failure in which there is only one occurrence of the name being substituted (‘Lois believes that Superman is an extraterrestrial’), but some direct reference theorists have tried to develop a more general notion of structure for these cases (Taschek 1995).

It is the handling of substitutivity puzzles that is the deciding issue between sense theories and direct reference theories of proper names. Sense theorists need to find a viable account of the senses of names and direct reference theorists need to find a persuasive account either of why substitutivity fails in cases such as (5), or else of why it gives such a convincing appearance of doing so.

Property

Most of the great philosophers have expressed views on property, its justification and limits, and especially on the justification of having private property; generally, one must understand these views against the background of the economic and social conditions of their times. Notable theories include first possession (roughly, 'whoever gets his or her hands on it justifiably owns it'), labour ('whoever made it deserves to own it'), utility and/or efficiency ('allowing people to own things is the most effective way of running society') and personality ('owning property is necessary for personal development').

Few thinkers now defend the first possession theory but all the other three have their contemporary supporters. Some philosophers combine two or more theories into multi-principled or 'pluralist' justifications of property ownership. Many express concern about wide gaps between rich and poor and argue for constraints on inequalities in property holdings.

1 Concept of property

The concept of property is understood in two main ways. First, it applies to material things such as tools, houses and land. Second, it applies to bundles of 'rights'. Most lawyers and philosophers stress the second understanding over the first. The first is too narrow to accommodate intangibles such as copyrights, patents and trademarks. Moreover, for purposes of legal and philosophical analysis the second understanding is more useful.

Here the word 'rights' covers many normative modalities (see Rights §2). Following Hohfeld and Honoré, the package of rights called 'property' includes: claim rights to possess, use and receive income; powers to transfer, waive and exclude; a disability (a no-power) of others to force a sale; liberty rights to consume or destroy; and immunity from expropriation by the government. It is probably a vain enterprise to try to specify necessary and sufficient conditions for all and only those 'rights' that pertain to property rather than, say, to contract or tort. Yet it is a worthy undertaking to try to identify those 'rights' that seem most central to property or those rules that create such 'rights'.

The second understanding of property finds favour for many reasons. It applies to widely different cultures. It is useful in both legal and philosophical analysis. It can accommodate both 'will' and 'interest' theories of rights. It can capture both full ownership and limited property rights (such as easements), and both tangible and intangible property. It permits distinguishing among different sorts of property depending on the identity of the rightholder. Thus, a single person or a corporation has *private* property, a tribe has *communal* property and a government has *public* or *state* property.

This explanation of the concept of property is neutral with respect to which kinds of things can be the subject of property rights. Few would defend slavery, which is the most extreme form of property in the bodies or persons of others. More disputed are whether people can have property rights in the whole of their own bodies, in bodily parts for use in transplantation, in information, in cultural practices, in welfare payments or other forms of government largesse, or in seabed resources or objects in outer space.

The approach of Guido Calabresi and Douglas Melamed (1972) to the notion of property, which philosopher-economists and lawyer-economists often use, is not conceptually distinct from that of Hohfeld (1919) and Honoré (1961). For Calabresi and Melamed the basic idea is an 'entitlement'. An entitlement is, roughly, an interest that the law does or should protect. Decisions must be made as to which entitlements to protect and how to protect them. As to the latter decision, the law may use what Calabresi and Melamed call 'property rules', 'liability rules' and 'rules of inalienability'. These technical terms can be restated in Hohfeld's vocabulary. If a person's entitlement is protected by a property rule, then others have a disability (a no-power) with regard to obtaining the entitlement except at a price agreed to by its holder. If a person's entitlement is protected by a liability rule, then others have a disability with regard to obtaining or reducing the value of the entitlement unless they compensate its holder by an officially determined amount. If a person's entitlement is protected by a rule of inalienability, its holder has no power to transfer the entitlement to others. The real value of Calabresi and Melamed's approach rests in the light that it sheds on the integration of property and tort, on its application to pollution control, on its sensitivity to distributional as well as efficiency considerations, and on the choice between

civil and criminal sanctions for violations of property rights.

2 History of theorizing about property

Many of the great philosophers have offered views on property. Plato actually expresses two different views (see Plato §§14, 17). In the *Republic* he portrays an ideal society in which the rulers and auxiliaries have political power but almost no private property. Ordinary citizens possess private property, with limits on unequal distribution, but have almost no political power. In contrast, the *Laws* depicts a practical, second-best society. It favours individual private possession with underlying communal ownership. Regulations maintain a roughly equal distribution of property.

Aristotle advocates private rather than communal ownership on grounds that relate to the smooth functioning of a society and its economy. His *Politics* fails, however, to show how property should, or can, be 'in a certain sense common, but, as a general rule, private'.

Locke, at least in the *Second Treatise*, offers a labour theory of property (see Locke, J. §10). The interpretation of his theory is disputed. It is unclear how much the theory rests on 'mixing' one's labour with unowned things, or on barring the idle from taking the benefit of the labourer's pains, and the extent to which the needs of others and restrictions on spoilage limit the acquisition of property by labour. It is also disputed whether Locke's theory is proto-capitalist or stems from some conception of natural law.

Hume and Bentham are the first important utilitarian theorists of property. For Hume (1739-40), utility in the sense of common interest explains how private property arises (see Hume, D. §§4-5). It also justifies the general institution of private property and specific rules of property law. Bentham (1802) understands utility as the balance of pleasure over pain, and views property in terms of expectations (see Bentham, J. §2). The security of expectations, rather than equality in distribution, is for Bentham the weightier consideration in favour of private property. Nevertheless, Bentham is sharply critical of the English law of property of his day.

Kant and Hegel are also linked, although less closely and in more complicated ways than Hume and Bentham. For Kant, as for Locke, a form of private property can exist in the state of nature (see Kant, I. §10). But Kant has a social contract theory under which only society can give individual possession full normative significance as private property. Hegel regards Kantian private property as excessively individualistic and belonging to the domain of 'abstract right' (see Hegel, G.W.F. §8). A more sophisticated form of property exists in 'civil society' - roughly, the social correlate of *laissez-faire* capitalism. Only in the 'state' does private property emerge fully transformed; private property, unequally distributed, still exists, but is subject to heavier state regulation in the organic interest of all citizens.

Marx dismisses Hegel's dialectical defence of private property as so much claptrap. Marx believes that capitalist production, not unequal distribution, is the more serious problem, because 'capitalism' distorts human relationships. In particular, private property under capitalism involves 'alienation' - that is, a separation of persons from nature, the products of their labour, other human beings and even themselves (see Alienation §4). *Pace* Marx, it is unclear that all forms of private property must involve alienation, or that alienation will be absent from the mature communist society that he envisages.

3 Systematic justifications of private property

First possession and entitlement. Attempts to justify the acquisition of property by being the first person to possess it have won few converts. The general difficulty is to show why first possession should support full ownership rather than limited rights of use. Specific difficulties include articulating which acts of possession count, explaining how long they must continue, and identifying the item or area possessed. Suppose that someone claims title to an acre of farmland by standing in one place for an hour. Why should that person not have to farm rather than merely stand, to remain there for a year rather than just an hour, and to perform appropriate acts over the entire acre rather than only on an area two feet square? To many these difficulties have no ready solution. Still, those sympathetic to the rights of aboriginal peoples sometimes invoke first possession.

A related account is the libertarian entitlement theory of Robert Nozick (1974). Nozick's position is hazy on which acts are appropriate acts of acquisition under his principle of justice in acquisition. The literature contains sharp

attacks on his position. Among them are objections as to how any individual can, by unilateral action, impose moral duties on others to refrain from using certain resources, worries about inequalities of property holdings, and scepticism that anyone living today has morally valid property rights by transfer from some original acquirer. Nozick has not responded to these attacks. Other libertarian theories are either grounded in economics or based on strong conceptions of freedom and individual rights (see Libertarianism §3).

Labour. More promising are efforts to recast the labour theory in terms of the desert of the labourer. Lawrence Becker and Stephen Munzer offer somewhat different accounts of a labour-desert principle.

Becker (1977) holds that if a worker adds value to the lives of others in some morally permissible way and without being required to do so, that person deserves a fitting benefit. Property rights may be the most fitting benefit, and which benefit is 'most fitting' depends on purposes. However, Becker's theory leaves it unclear which purposes (for example, an attempt to gain property rights?) and whose purposes (the labourer's or those of other individuals?) are relevant. Also, he does not show why purpose should be the sole test of fittingness. Nevertheless, Becker rightly insists that losses inflicted by the labourer's work require some reduction in property rights or some offsetting compensation or taxation.

Munzer (1990) argues that if workers use their bodies to produce something or provide a service, then they have a *prima facie* claim to deserve property rights in the product or in wages. This claim is qualified by scarcity, by the needs and rights of others, and by some post-acquisition changes in situation. Restrictions on transfer may also apply. Moreover, since work is a social activity, a wage policy is in order that makes wages commensurate so far as possible with desert. The heavy qualifications that surround this version of the labour theory support moderate egalitarianism rather than the wide disparities in income and wealth that libertarian theories allow. Critics of Munzer's labour-desert principle have objected that its intellectual underpinnings are not sufficiently clear and that in both theory and practice no precise correlations exist between desert claims and property rights (see Desert and merit).

Utility and efficiency. Contemporary justifications of this sort owe a distant obligation to Hume and Bentham. These justifications often stress 'efficiency', which does not allow interpersonal comparison of individual preference satisfaction, over 'utility', which does allow them. Because of the invocation of efficiency, the most sophisticated advocates are frequently economists or academic lawyers influenced by economics rather than philosophers.

Utility and efficiency can, given some plausible assumptions about individuals' preferences, justify some public property as well as some rights of private property. They tend (again given certain assumptions about preferences) to justify moderate egalitarianism rather than highly unequal distributions of private property. However, more detailed information is needed to show how utility and efficiency can justify particular rules of property law or radical changes in existing property institutions. Perhaps the most influential theoretical result of applying efficiency to the law of nuisance bears the sobriquet 'Coase's Theorem' (Coase 1960). It holds that, under perfect competition and perfect information and with costless transactions, an efficient allocation of resources will result no matter what the decision of the courts concerning liability for damage.

Personality. Contrary to some reports, the personality theory of property did not die with Hegel and the British neo-Hegelians. The basic idea is that people need at least some private property in order to develop healthy character structures. The account of 'property for personhood' by Margaret Radin (1982) is probably the best known and most fully developed contemporary theory of this sort. She applies her theory to many practical legal problems, but some readers find the foundations of her account no clearer that those of Hegel. Her books also suggest that some things are so personal that they ought not to be property or 'commodities' at all.

Pluralist theories. The variety of possible justifications of property has suggested to some writers that the most plausible account of property is 'pluralist' - that is, contains two or more irreducible principles. Becker and Munzer explicitly embrace pluralist accounts. Other writers do so implicitly. Some critics dismiss such pluralism as eclectic. Other critics contend that if it is impossible to show that the principles never conflict, it is necessary to establish that conflict between principles is logically consistent and otherwise free from objection. Further, it may be harder to apply a pluralist theory rather than a unitary theory to practical problems. Still, those who favour a unitary theory - a theory with a single principle or at least a single supreme principle - must show how it can

accommodate the complexity of considered moral judgments concerning property. For anyone who shares Proudhon's worry that property is theft (1841), justification remains the key problem in the theory of property (see Proudhon, P.-J.).

4 Constraints on the distribution of property

Justice and equality. The liberal tradition in political theory, stemming particularly from Mill, often tries to limit inequalities of property holdings (see Mill, J.S. §§11-12). The limitation can take the form of a side constraint or, in a pluralist theory, of a separate principle of justice and equality. Few philosophers argue for strictly equal holdings. More modest is the 'difference principle' of John Rawls (1971; 1993) (see Rawls, J. §§1-2). Applied to property, this principle would hold that differences in holdings are justifiable only if they are to the greatest benefit of the least advantaged. A related view might concentrate on both the floor and the ceiling: Everyone should be ensured a minimum amount of property, and remaining inequalities, if any, should not undermine a fully human life for anyone in society.

Absence of exploitation. The radical tradition in political theory, traceable especially to Marx, stresses the need to eliminate exploitation and other differences in power that derive from unequal property holdings. Roughly, persons are exploited if others secure a benefit by using them as a tool or resource so as to cause them serious harm. Exploitation theory often concentrates as much on problems of economic production as it does on the real or imagined evils of unequal distributions of property. The 'Critical Legal Studies movement', in some of its forms, objects to exploitation and differences in power as they relate to property (see Critical legal studies). More rigorous accounts of exploitation come from the work of John E. Roemer (1982).

Property theory

Traditionally, a property theory is a theory of abstract entities that can be predicated of things. A theory of properties in this sense is a theory of predication - just as a theory of classes or sets is a theory of membership. In a formal theory of predication, properties are taken to correspond to some (or all) one-place predicate expressions. In addition to properties, it is usually assumed that there are n-ary relations that correspond to some (or all) n-place predicate expressions (for $n \geq 2$*). A theory of properties is then also a theory of relations.*

In this entry we shall use the traditional labels 'realism' and 'conceptualism' as a convenient way to classify theories. In natural *realism, where properties and relations are the physical, or natural, causal structures involved in the laws of nature, properties and relations correspond to only some predicate expressions, whereas in* logical *realism properties and relations are generally assumed to correspond to all predicate expressions.*

Not all theories of predication take properties and relations to be the universals that predicates stand for in their role as predicates. The universals of conceptualism, for example, are unsaturated concepts in the sense of cognitive capacities that are exercised (saturated) in thought and speech. Properties and relations in the sense of intensional Platonic objects may still correspond to predicate expressions, as they do in conceptual intensional realism, *but only indirectly as the intensional contents of the concepts that predicates stand for in their role as predicates. In that case, instead of properties and relations being what predicates stand for directly, they are what nominalized predicates denote as abstract singular terms. It is in this way that concepts - such as those that the predicate phrases 'is wise', 'is triangular' and 'is identical with' stand for - are distinguished from the properties and relations that are their intensional contents - such as those that are denoted by the abstract singular terms 'wisdom', 'triangularity' and 'identity', respectively. Once properties are represented by abstract singular terms, concepts can be predicated of them, and, in particular, a concept can be predicated of the property that is its intensional content. For example, the concept represented by 'is a property' can be predicated of the property denoted by the abstract noun phrase 'being a property', so that 'Being a property is a property' (or, 'The property of being a property is a property') becomes well-formed. In this way, however, we are confronted with Russell's paradox of (the property of) being a non-self-predicable property, which is the intensional content of the concept represented by 'is a non-self-predicable property'. That is, the property of being a non-self-predicable property both falls and does not fall under the concept of being a non-self-predicable property (and therefore both falls and does not fall under the concept of being self-predicable).*

1 Logical realism and conceptualism in second-order logic

Frege (1879) was among the first to formalize a theory of properties and relations. His theory amounts to a version of standard second-order predicate logic (see Second- and higher-order logics). By 'standard' here is meant an axiomatic formulation that contains among its valid theses all instances of the full impredicative comprehension principle (CP), in which bound predicate variables may occur, so that a property or relation can be specified in terms of a totality to which it belongs. Formally, CP is described as follows:

$$(\exists F)(\forall x_1)\ldots(\forall x_n)[F(x_1,\ldots,x_n) \leftrightarrow \phi],$$

where *F* is an *n*-place predicate variable not occurring free in ϕ and $x_1,\ldots,x_n$ are distinct individual variables.

By CP, every open formula ϕ containing n free individual variables is said to represent a property or relation, which, using the λ-abstraction operator (see Lambda calculus), may also be represented by a λ-abstract, $[\lambda x_1 \ldots x_n \phi]$, as a complex n-place predicate expression. (Here λ is an operator that binds *n* individual variables $x_1,\ldots,x_n$, and when affixed to a formula ϕ results in a complex predicate expression in which all of the occurrences of $x_1,\ldots,x_n$ in ϕ are bound. For example, the complex predicate of being objects *x* and *y* such that

$$F(x,y) \rightarrow (\exists G)[G(x,y) \wedge G(y,x)]$$

can be represented by the $\lambda\text{-abstract}$

$$\{\lambda xy(F(x,y) \rightarrow (\exists G)[G(x,y) \wedge G(y,x)]).)$$

The λ-abstract is taken as a valid substituend of the bound n-place predicate variables in universal instantiation

and to satisfy the principle of λ-conversion,

$$(\forall x_1)\ldots(\forall x_n)([\lambda x_1 \ldots x_n \phi](x_1, \ldots, x_n) \leftrightarrow \phi).$$

Because every open formula constructed from atomic formulas in terms of the logical connectives - including quantifiers for individual and predicate variables - is assumed to represent a property or relation in such a theory, the theory is said to amount to a version of ‘logical realism’ (regarding the existence of universals).

Not every property theory or formal theory of predication will validate CP; that is, not every open formula need represent a property or relation in such a theory. In standard *predicative* second-order logic, for example, formulas containing bound predicate variables are not allowed to occur in the comprehension principle - a constraint that is supposed to restrict the assumption of properties to those that can be represented by first-order formulas where predicate quantifiers do not occur. No λ-abstract in which predicate quantifiers occur will be well-formed in such a theory, and the principle of universal instantiation for predicate quantifiers will be restricted to formulas that contain no bound predicate variables. Formulas with predicate quantifiers can be used to specify properties and relations in *ramified* predicative second-order logic - but only as values of predicate variables of a higher ‘level’ in the ramified hierarchy, so that no property or relation can be specified in terms of a totality encompassing that property or relation. (See Church 1956: §58.) The motivation for such a restriction is unclear, however, if properties and relations are assumed to exist independently of language and thought. In fact, a substitutional interpretation of predicate quantifiers, with predicate variables having only first-order formulas as their substituends, can be given for standard predicative second-order logic - and a similar related interpretation can be given for its ramification - so that the restriction is equivalent to a nominalistic theory of predication, according to which there are no universals - that is, no properties or relations - beyond the predicate expressions of first-order languages. (See Cocchiarella 1986: ch. 1; 1989: §3.)

In a constructive conceptualist theory of predication, where concepts are understood as the rule-following cognitive capacities underlying the use of predicate expressions, the intent of such a restriction on predicate quantifiers is to preclude the possibility of forming impredicative concepts, that is, concepts that presuppose or conceptually involve a totality to which they belong (such as the concept of a least upper bound of a class of real numbers that has upper bounds). The predicative logic of ‘constructive conceptualism’ can be formulated as a nonstandard predicative second-order logic in which not all predicate expressions - now including all λ-abstracts, even those in which bound predicate variables occur - are assumed to represent a predicative concept. Such a logic is ‘free of existential presuppositions’ regarding predicate expressions; and, in particular, no presumption is made independently of meaning postulates as to which predicate constants stand for predicative concepts and which do not. Such a predicative logic can also be ramified, so that concepts can be formed in terms of quantification over concepts formed at a prior ‘stage’ of the ramified hierarchy; but each ‘stage’ of the ramification differs from the ‘levels’ of ramification in standard ramified second-order logic in being ‘free of existential presuppositions’ regarding predicate expressions. Such a nonstandard predicative logic can also be seen as part of a pattern of conceptual development in which impredicative concept-formation becomes possible, that is, as leading to the validation of CP in a ‘holistic’ conceptualism - if, as seems warranted given the history of mathematics, a pattern of reflective abstraction in which an idealized transition to a limit is acknowledged to be conceptually possible. (See Cocchiarella 1986: ch. 2; 1989: §§7-8.)

The nonstandard predicative logic of constructive conceptualism, and, similarly, the impredicative logic of holistic conceptualism, will contain a property theory if it is assumed - in a framework of conceptual intensional realism, for example - that properties and relations are intensional objects and that most (if not all) concepts will have such an intensional object as their intensional content. As intensional objects, properties and relations will then be constituents of propositions as the intensional contents of sentences. But, as already noted, as intensional objects, properties and relations will be the objects that nominalized predicates denote as abstract singular terms (a topic we will return to in §4 below).

2 Natural realism

There is another conception of properties and relations for which it is inappropriate to construe them as intensional objects, and in particular as constituents of propositions. On this alternative, properties and relations are components of states of affairs (which are part of the natural order, as opposed to propositions, which are part of

the intensional order), and in that regard they are the physical, or natural, properties and relations involved in the laws of nature. Such physical or natural properties and relations may correspond to some of our concepts or predicate expressions, but in general not every concept or predicate expression will even purport to represent, still less have, such a natural property or relation corresponding to it. No comprehension principle will be valid when the predicate quantifier is taken to refer to a natural property or relation, accordingly, and any assumption that a formula represents a natural property or relation will always amount at best to an empirical hypothesis of an applied scientific theory.

Traditionally (as, for example, in Aristotle's theory), natural properties were said to exist only *in re*, that is, only in the concrete objects that have such properties, which means that

$$(\forall^{N} F)(\exists x_1)\dots(\exists x_k)F(x_1,\dots,x_k),$$

where '$\forall^{N}$' is a universal quantifier that refers to natural properties and relations when affixed to predicate variables, is valid in such a theory. For this reason, the theory may be called a 'moderate realism'. This thesis is too strong, however, if such a theory is to allow for physical or natural properties and relations - such as those of certain transuranic elements - that *could* be realized in our world as a matter of a natural or causal possibility, even though in fact they never are. In a *modal* moderate realism, the thesis is weakened to

$$(\forall^{N} F)\Diamond^{c}(\exists^{e} x_1)\dots(\exists^{e} x_k)F(x_1,\dots,x_k),$$

where '$\Diamond^{c}$' is a modal operator for a causal or natural possibility, and '$\exists^{e}$' is an existential quantifier that refers only to existing (concrete) objects when affixed to individual variables - and where individual variables and singular terms are otherwise 'free of such existential presuppositions'. The 'concept' of (concrete) existence, defined as

$$E!(x) =_{\mathrm{df}} (\exists^{e} y)(x = y),$$

does not represent a natural property in such a theory - though an abstract property in the sense of an intensional object may be assumed as the intensional content of such a concept in conceptual intensional realism (which can be consistently combined with a natural realism in the general framework of 'conceptual realism'). (See Free logics for more on the logic of singular terms that are 'free of existential presuppositions'.)

3 Actualism and possibilism in modal logical realism

Existence is a property in 'modal logical realism', which is based on a logical or metaphysical notion of possibility and necessity (represented by '$\Diamond$' and '$\Box$'; see Modal logic), and which can be either actualist or possibilist. In *possibilist* modal logical realism, individual variables bound by '$\forall$' or '$\exists$' have possible, as well as actual, objects as their values (and abstract objects as well if such are assumed), and the statement that 'Some things do not exist', formulated as $(\exists x)\neg E!(x)$, is well-formed and meaningful. Predicate variables bound by these quantifiers refer to properties that might apply to nonexisting, as well as existing, objects - though some properties, such as $[\lambda x \neg E(x)]$, apply only to nonexisting objects, whereas others, such as $[\lambda x E(x)]$, apply only to existing (concrete) objects.

In *actualism*, only the actualist quantifiers '$\forall^{e}$' and '$\exists^{e}$' are allowed, so that individual variables bound by these quantifiers have only actual (existing, concrete) objects as their values, and predicate variables bound by these quantifiers have only 'existence-entailing' (e-)properties and (e-)relations as their values - and hence

$$(\forall^{e} F)\Box[F(x_1,\dots,x_n) \rightarrow E!(x_1) \wedge \dots \wedge E!(x_n)]$$

is valid in actualism. Unlike the situation in possibilism, not every open formula or λ-abstract represents an e-property or e-relation, which means that the comprehension principle for actualist modal logical realism must be suitably restricted. (See Cocchiarella 1989: §10.)

4 Nominalized predicates in property theories

In addition to the question of which open formulas or λ-abstracts can be said to represent properties or relations (and can be valid substituends of quantified predicate variables), property theories also differ on the question of whether or not properties and relations have an individual (or 'objectual') as well as a predicable nature, and in particular on whether or not they can also have properties and be 'logical subjects' of predication the way objects

in general are. In Frege's theory, for example, properties and relations are functions from objects to truth-values, where all functions, according to Frege, have an 'unsaturated' nature - a nature that categorially precludes them from being objects, all of which have a saturated nature. Even if predication is not explained in terms of functionality, however, properties and relations can still be construed as having an unsaturated nature that precludes them from being objects. In Wittgenstein's version of 'logical atomism' (see Wittgenstein 1922), for example, and in natural realism as well, material or natural properties and relations are the nexuses (or modes of configuration) of states of affairs, and as such they cannot also be objects configured in states of affairs (see Wittgenstein, L.; Logical atomism §1). Similarly, in conceptualism, predicable concepts, as rule-following cognitive structures underlying the use of predicate expressions, are unsaturated cognitive capacities whose exercise (or saturation) in thought and speech is what informs our speech and mental acts with a predicable nature - which means that concepts have only a predicable and not also an individual (or 'objectual') nature. This does not preclude the intensional content of concepts - which are also called properties and relations in the sense of the Platonist, rather than the Aristotelian, tradition - from being objects; namely, the abstract objects that nominalized predicates denote as abstract singular terms, as opposed to the unsaturated concepts that predicates stand for in their role as predicates. Frege held a view something like this in his version of logicism - except that, because of his commitment to an extensional logic, Frege took the objects denoted by abstract singular terms to be classes rather than intensional objects. The important point in all of these views is that even though the universals that predicate expressions stand for in a given formal theory of predication are not themselves objects (values of the individual variables), some (or all) of them may nevertheless have objects correlated with them as the denotata of the same predicate expressions nominalized as abstract singular terms.

The usual way of representing the nominalization of a simple or complex predicate expression as an abstract singular term is by simply deleting the parentheses and commas that are part of that expression's role as a predicate. Thus, whereas $F(x)$ and $R(x,y)$ are formulas in which F and R occur only as predicates, $G(F)$ and $G(R)$ are formulas in which they occur only as singular terms; and in $F(F)$ and $R(F,R)$, they occur first as predicates and then as singular terms. Similarly, where ϕ is a formula, $[\lambda x\phi]([\lambda x\phi])$ is a formula in which $[\lambda x\phi]$ occurs first as a predicate and then as a singular term. A stronger comprehension principle (CP^*_λ) can now be formulated in terms of identity,

$$(\exists F)([\lambda x_1 \dots x_n \phi] = F),$$

from which, by Leibniz's law (applied now even to abstract singular terms), CP is a consequence.

Bertrand Russell, like Frege, also maintained a version of logical realism; but, unlike Frege, Russell rejected the idea that properties and relations have an unsaturated nature that precludes them from being objects (even though he explained the unity of a proposition in terms of a relation occurring only as a relation and not also as an object). Unlike the situation for Frege, in other words, for Russell a nominalized predicate denotes the same property or relation as an abstract singular term that the predicate otherwise stands for in its role as a predicate. This difference is unimportant as far as Russell's paradox of predication is concerned, however, because the paradox, which can be derived from the following instance of CP (and hence from CP^*_λ) in which a nominalized predicate occurs as abstract singular terms,

$$(\exists F)(\forall x)[F(x) \leftrightarrow (\exists G)(x = G \wedge \neg G(x))],$$

applies to both Frege's and Russell's views of predicates and their nominalizations. Russell's way out of his paradox was the ramified theory of types, which involves grammatically categorizing predicate expressions not only in terms of the hierarchy of 'levels' of ramified second-order logic but also in terms of a 'vertical' hierarchy of orders in which predicates that take nominalized predicates as singular terms must always be of a higher order than the latter (see Theory of types).

Later authors, such as L. Chwistek and F. Ramsey, noted that ramification into levels (of the 'horizontal' hierarchy) is not needed to avoid logical paradoxes such as Russell's, and that a simple theory of types suffices instead - though others, such as A. Church, maintain that the ramified, 'horizontal' hierarchy is still needed for certain intensional or semantic paradoxes. R. Montague (1974) developed an intensional logic for natural language based on a version of simple type theory that was originally formulated by Church. Montague extended Church's theory by adding to it intension- and extension-forming operators (patterned after Frege's *Sinn*/*Bedeutung*

distinction; see Frege, G. §3), ‘ $\wedge$ ’ and ‘ $\vee$ ’, so that where ξ is a well-formed expression of the theory, $^\wedge\xi$ stands for the intension (or sense) of ξ, and $^\vee\xi$ stands for its extension (and hence $^{\vee\wedge}\xi = \xi$ is valid). Properties and relations of entities of types $t_1, \ldots, t_n$ are then taken as the intensions (or senses) of the classes of n-tuples of those types, and the predication of a property or relation (in intension) is defined as membership of the class that the property or relation has as its extension.

5 Conceptual intensional realism

There are other ways to avoid Russell’s paradox besides type theory. One way is to return to standard second-order logic with nominalized predicates as abstract singular terms and restrict λ-abstracts so that only those that can be homogeneously (h-)stratified from an external (metalinguistic) point of view are well-formed. (An expression is ‘h-stratified’ if it is possible to assign natural numbers to the predicates and singular terms occurring in it so that singular terms flanking the identity sign, as well as all of the subject expressions of any predicate expression occurring in it, are assigned the same number, with the predicate itself assigned the successor of that number.) This amounts to restricting the comprehension principle CP^*_λ so that even though the above instance of CP for Russell’s paradox is well-formed, it is not provable, because the λ-abstract

$$[\lambda x(\exists G)(x = G \wedge \neg G(x))]$$

is not h-stratified. The resulting system is equiconsistent with the simple theory of types.

Another way to avoid Russell’s paradox in the context of second-order logic with nominalized predicates is to allow all λ-abstracts, h-stratified or not, to be well-formed and to retain the full comprehension principle CP^*_λ, but allow the first-order part of the logic to be free of existential presuppositions regarding singular terms. The principle of λ-conversion must then be qualified as follows,

$$[\lambda x_1 \ldots x_n \phi](a_1, \ldots, a_n) \leftrightarrow$$
$$(\exists x_1) \ldots (\exists x_n)(a_1 = x_1 \wedge \ldots \wedge a_n = x_n \wedge \phi),$$

where no x_i is free in any a_j, for all i, j such that $1 \leq i \leq j \leq n$. Then, even though

$$(\exists F)([\lambda x(\exists G)(x = G \wedge \neg G(x))] = F)$$

is provable as an instance of CP^*_λ, that is, even though $[\lambda x(\exists G)(x = G \wedge \neg G(x))]$ stands for a predicable concept in its role as a predicate, all that follows by the argument for Russell’s paradox is that it cannot also denote an object in its role as an abstract singular term, because

$$\neg(\exists y)([\lambda x(\exists G)(x = G \wedge \neg G(x))] = y)$$

is also provable. In conceptual intensional realism, this result means that the attempt to ‘object-ify’ the content (in the sense at least of the truth-conditions) determined by the predicable concept represented by $[\lambda x(\exists G)(x = G \wedge \neg G(x))]$ as an intensional object (or property in the Platonist tradition) must fail. In a reconstruction of Frege’s extensional theory, it means that there is no extension (class) corresponding to the property in question. This is not possible in a reconstruction of Russell’s view, however, because for Russell every nominalized predicate denotes the same property that the predicate stands for. (See Russell 1903: §49.)

Finally, there are also strictly first-order property theories. Some are developed along the lines of Zermelo-Fraenkel set theory, with membership replaced by exemplification as a predication relation, and with the deletion at least of the axiom of extensionality (see Schock 1969), and sometimes also of the axiom of foundation (see Jubien 1989). (See Set theory, different systems of.) Some authors prefer to defer assuming specific axioms for predication and simply extend first-order logic to include nominalized predicates as abstract singular terms, leaving the choice open of how predication might be axiomatically developed as a relation regarding the denotata of such singular terms. (See Bealer and Mönnich 1989.) Others develop a first-order theory of properties based on assuming a similarity between revisionist theories of truth and predication as a first-order relation (see Turner 1987).

Prophecy

Most people associate prophecy with prognostication. However, an understanding of philosophical theories of prophecy requires that we recognize the full range of functions that a prophet may serve: oracle, cognizer of the divine, moral and social critic, teacher, political leader, legislator, miracle-worker.

A recurring and fundamental issue, dating to ancient times, is whether prophecy is to be explained naturally or supernaturally. The Muslim philosopher al-Farabi and the Jewish philosopher Maimonides exemplify the naturalist orientation. They understood prophecy as an imaginative 'imitation' or translation of scientific and philosophical truths. Their accounts emphasize not only the intellectual but also the political, legislative and educational functions of prophecy. The Muslim al-Ghazali and the Christian Thomas Aquinas illustrate the supernatural approach, albeit in greatly different ways.

The proposition that biblical prophetic experiences convey scientific and metaphysical knowledge was attacked in varied ways in the modern period. In religious traditions, prophets have been replaced as sources of religious knowledge by either mystics, or books and authoritative interpreters. However, theories of prophecy are linked to important issues about religious language, miracles, the nature of God, the ends of life, and the character of religion.

1 Functions of the prophet

The term 'prophecy' immediately conjures up the ideas of 'prognostication' and 'divination'. However, most philosophical accounts of prophecy, particularly since medieval times, presuppose a far broader conception of the prophet's function. The Greek word *prophetes*, from which the English derives, denotes one who 'speaks for' a god, who imparts divine messages; and in religious traditions, these messages are of various kinds.

While biblical prophets foretell events in the future, religious traditions also imply that they possess divinely imparted knowledge about events in the distant past (for example, creation, or the history of the Jews). According to medieval philosophers, they also possess special knowledge of the structure and workings of the cosmos. Moreover, they bring a moral message. Prophets also perform miracles. Finally, of course, they experience the divine presence in visions, auditions or dreams (see, for example, Isaiah 6). These different functions of the prophet constitute the 'data' that philosophical theories of prophecy have sought to explain.

2 Ancient theories: prophecy and veridical dreams

Philosophical speculation about prophecy began with ancient theories about divination and veridical dreams. Democritus asserted that in dreams, 'images' (*eidōla*) - possibly originating from statues of gods - affect the soul and divulge the future. Aristotle, during an early Platonic stage of his thought, maintained that the soul has a capacity for divination by virtue of its godlike nature. Later, in *On Divination in Sleep* (one of the *Short Natural Treatises*), he maintained that prophecy does not come from a god, since it is not 'the best and the wisest' who experience veridical dreams, but rather the melancholic. Aristotle explored various naturalistic accounts of this phenomenon. Ironically, the notion that prophecy need not occur to the best and the wisest, which Aristotle cited to support naturalism, later became associated with the supernatural view that God can turn whomever he wants into a prophet. An Arabic recension of the *Short Natural Treatises* created the false impression that Aristotle had traced veridical dreams to a cosmic intellect. This misconception influenced later developments among Muslim and Jewish philosophers.

3 Medieval theories: Muslim philosophers

Medieval philosophers debated the extent to which God directly intervenes in the world. Prophecy was implicated in this general debate. Is prophecy divinely bestowed, or is it a natural human attainment? Is prophetic knowledge continuous with everyday or scientific cognition, or is it of a special kind? What faculties must one possess to attain prophecy? Is special preparation required? What is the significance of prophetic imagery? What is meant by divine speech? Philosophers' answers to these questions were anchored in their general metaphysical and epistemological theories; the theory of prophecy is a window into medieval epistemology, which in turn is rooted in medieval metaphysics.

A vital figure in the development of medieval theories of prophecy was the Arabic philosopher al-Farabi. Although discrepancies exist among his various writings and he does not always use the term ‘prophecy’ where one might expect it, the common understanding of al-Farabi as a ‘Neoplatonized Aristotelian’ may be summarized as follows (see al-Farabi §2). Prophecy is attained by individuals of superior intellect by means of an ‘emanation’ from the ‘active intellect’. This emanation flows first to the individual’s passive (potential) intellect - thus actualizing the rational faculty - and then to the imaginative faculty. The imaginative faculty both receives and manipulates physical impressions. The prophet’s (perfected) imagination frames, or represents, scientific and metaphysical truths in sensory images. This enables the prophet to convey aspects of these truths to the untutored masses. Imagination - in concert with the ‘practical’ intellect, which has also received the overflow - is associated as well with lawgiving and political skill. Al-Farabi’s theory expresses his thesis that religion is an imaginative translation - or ‘imitation’- of scientific and metaphysical truth. The fusion of philosophy, law and politics in al-Farabi’s thought is modelled after the philosopher-ruler of Plato’s *Republic*. (In some places, we should note, al-Farabi calls the philosophical, nonimaginative reception of truth ‘revelation’ and ranks it above prophecy.) Veridical dreams and divination, as products of imagination, bear resemblance to prophecy.

While sharing al-Farabi’s naturalism, Ibn Sina (Avicenna) held that the active intellect can impart genuine theoretical knowledge even of forms that the individual did not acquire by abstraction (see Ibn Sina §§2-3, 5). Prophecy of this elevated type is due to a special ‘intuition’ or ‘insight’, and so Ibn Sina’s theory is sometimes characterized as mystical. Reflecting, like al-Farabi, an emphasis on the prophet’s political function, Ibn Sina believed that only prophets can create a bond between people, and he regarded the existence of prophetic lawgivers as a teleological provision of nature. He also developed a naturalistic account of how prophets work miracles: an excellent or noble soul may act upon physical matter, even as the soul acts upon one’s body.

Against al-Farabi and Ibn Sina, other Muslim thinkers refused to see prophecy as naturally acquired. The Ash‘arite al-Ghazali (§4) believed that God is the only true cause of events (see Occasionalism §1). Hence God directly conveys prophetic knowledge: he imparts it to the angels, who pass it on to the prophet. Al-Ghazali regarded naturalistic philosophical approaches to prophecy as contrary to Islam, though he fell into various contradictions (for example, he recognized that the natural faculties of the soul play *some* role in prophecy). At points he also denied the political function of the prophet. Al-Ghazali believed that sciences are possible only by virtue of divine assistance, thereby significantly expanding the range of prophetic phenomena in accord with his metaphysics of divine causation.

4 Medieval theories: Jewish and Christian philosophers

Al-Farabi’s theory of prophecy was adopted, with alterations and with the addition of motifs characteristic of Ibn Sina, by the Jewish philosopher Moses Maimonides (§5) (*Guide to the Perplexed* II, chaps 32-48). Maimonides believed prophecy to be a natural process: ‘an overflow’ (emanation) from God through the intermediation of the active intellect towards the rational faculty and thence the imaginative faculty. (He allowed for a ‘miraculous withholding’ of prophecy from a qualified individual, but then again any natural process is subject to miracles.) The prophets’ possession of imagination in combination with intellect sets them apart from philosophers, while their possessing philosophy in addition to imagination sets them off from soothsayers, diviners and statesmen. The prophecy of Moses is said by Maimonides to be an exception to his general account, but scholars have debated exactly where the difference lies.

Thus, Maimonides and al-Farabi take the object of prophetic knowledge to be natural science and metaphysics. While they recognize differing levels of prophecy, they require the prophet to have satisfied intellectual and not only moral prerequisites. Knowledge of the future depends on a combination of scientific knowledge and imagination. Both al-Farabi and Maimonides regard intellectual perfection, or perhaps intellectual-cum-political perfection, as the most noble end of human life; hence the highest type of prophet represents the most nearly perfect individual.

Maimonides adopts a striking method of biblical exegesis and a distinctive ontology of prophetic images. Prophetic language, as a product of imagination, is a figurative couching for scientific and religious claims and is utilized to communicate with the masses. Thus, Ezekiel’s account of the chariot conveys for Maimonides the metaphysics of Neoplatonized Aristotelianism (*Guide to the Perplexed* III, chaps 1-8). The prophets’ depiction of God in anthropomorphic terms likewise results from imagination (which Maimonides sometimes hints is needed

even to facilitate the prophet's own apprehension). The 'sensory' objects in prophetic dreams and visions are products of imagination, not extramental existents.

Alexander Altmann (1978) has observed that, because Islamic and Jewish philosophers believed that every natural event, including scientific and philosophical cognition, results from a cosmic system of emanations tracing ultimately to God, naturalism about prophecy and providence was more religiously palatable to them than to thinkers whose metaphysics distinguishes sharply between divine activity and the natural order. Nevertheless, medieval critics found naturalism religiously unsatisfying and its accompanying figurative construal of biblical language exegetically implausible. Questions also arose about how, in the absence of direct divine aid, a prophet could predict events with the kind of detail that infuses biblical prophecies, especially in the case of predictions that entail knowledge of 'future contingents', the future free actions of human beings. In addition, the capacity of the prophet to acquire truths that reason cannot - for example, the belief in creation *ex nihilo* (*Guide to the Perplexed* II, ch. 25) - is hard to explain if prophetic knowledge issues naturally from normal philosophical and scientific reasoning. (However, a naturalistic view might allow for a special direct or intuitive knowledge, as per Ibn Sina.)

Several Jewish philosophers before and after Maimonides, such as Judah Halevi and Hasdai Crescas are often thought to have adopted a supernatural view of prophecy. In truth, their theories are ambiguous. Isaac Abravanel's theory is perhaps a better example of a Jewish supernaturalist account of prophecy (see Isaac Abravanel §2).

Christian philosophical treatments of prophecy include Augustine's *De Genesi ad litteram (The Literal Meaning of Genesis)* XII and Aquinas' *Quaestiones disputatae de veritate (Disputed Questions on Truth)*, q.12. Aquinas, as distinct from the naturalists, held that prophecy is a *donum Dei*, a pure gift of God. Prophecy results from unmerited grace, and God might even bestow it on someone who seems unfit. This supernatural account is qualified in several ways. For example, Aquinas recognizes naturalistic explanations of veridical dreams and pagan prophecies; also, when God bestows prophecy on the unfit, he does so by improving the individual's intellectual and imaginative faculties, whence prophecy ensues naturally. (God's activity seems to be further mediated by angelic activity.) Aquinas ignores the political function of prophecy so salient in Islamic accounts and in Maimonides' theory. Altmann (1978) has related Aquinas' theory to his rejection of much of Ibn Sina's ontology.

5 Modern approaches

In the modern period, the epistemic value of prophetic utterances came under varied attacks. Turning Maimonides' emphasis on imagination against him, Benedict de Spinoza (§14) wrote that 'the prophets were endowed with unusually vivid imaginations, and not with unusually perfect minds'. Their scientific and philosophical beliefs merely reflected their own dispositions and prior opinions. Hence 'we are not at all bound to trust them in matters of intellect'. Spinoza's claims signalled the eclipse of the medieval position that prophecy delivers truth, as well as of its concomitant enterprise, the philosophical exegesis of Scripture (*Theologico-Political Treatise*: ch. 2).

The epistemological problem of authenticating prophecy had been well known to medieval philosophers, but subsequently the challenge to validate claims to revelation assumed a more antagonistic cast even on the part of believers. Thomas Hobbes attacked 'visions' as mere daydreams, and remarked famously that to say God has spoken to a person in a dream is 'no more than to say he dreamed that God spake to him'. In the absence of miracles, he said, we have no way to distinguish true revelation (1651: III, ch. 32). John Locke (§7), though himself a believer in divine revelation, held that 'firmness of persuasion is no proof that any proposition is from God' and insisted that a person must use reason 'to enable him to judge of his inspirations, whether they be of *divine* original or no' (1689: IV.xviii-xix).

Eminent thinkers, such as Isaac Newton (§7), accepted the truth of biblical prophecies, arguing that the fulfilment of some gave proof that the others will be fulfilled as well. Declarations that prophecies had been fulfilled were often impugned on the grounds that biblical prophecies were too obscure or ambiguous to be tested. Advancing a more general critique, David Hume (§2) concluded his classic argument against accepting reports of miracles by extending his distrust to reports of true prophecies: 'all prophecies [that is, true predictions not based on induction]

are real miracles' (1748, 1751: sect. X).

With time, various theorists assimilated or reduced prophecy to such categories as ecstasy (an identification already made by the ancients), psychosis, poetic inspiration, hallucination, fabrication and demagoguery. Anthropologists viewed biblical prophecy as a phenomenon with cognates in many cultures, thereby diminishing any special claims of the prophets of the Bible and Qur'an. Even in theological circles, a distinction eventually emerged between the experience of (divine) presence and the experience of content. The content of a prophecy, on this account, represents a subjective, culturally conditioned human response to the experience of presence. Although the medieval view that the prophet exercises imagination also implied prophetic subjectivity, the modern approach implied a denigration of prophetic claims to objective truth and stressed the ethical response rather than the purely cognitive.

These varied challenges to traditional views often went along with deep admiration for the ethical thrust of prophetic religion, and theories respectful of prophecy continued to appear within theological frameworks. However, the overall contrast with medieval times is dramatic.

6 Prophecy in contemporary religion and philosophy of religion

It is sometimes said that prophecy differs from mysticism in its emphasis on God's word and communication of it. Assuming this distinction, we might say that, in the major religions, the role of prophets has been overshadowed by two things: at the one pole, mystics and, at the other, as Hobbes long ago noted, books and authoritative interpreters. Mystics and texts have thus become the primary medium of revelation. Prophecy also figures little in twentieth-century analytically oriented treatments of religion, though there has been some discussion of prophecy in connection with the alleged incompatibility of divine foreknowledge and human free will (see Omniscience §§3-4). Concepts connected to prophecy - revelation, mystical experience, miracles, the paranormal - are explored extensively by philosophers, but usually with scant or no reference to prophecy *per se*. All this is surprising in so far as the claims of traditional theism ultimately rest on the thesis that God communicates with human beings.

Propositional attitude statements

Propositional attitude statements - statements about our beliefs, desires, hopes and fears - exhibit certain logical peculiarities. For example, in apparent violation of Leibniz's law of the indiscernibility of identicals, we cannot freely substitute expressions which designate the same object within such statements. According to Leibniz's law, every instance of the following scheme is valid:

a = b
*F(*a*)*
*Therefore, F(*b*)*

The validity of Leibniz's law seems beyond question. It says, in effect, that if an object has a certain property, then anything identical to that object also has that property. Valid instances abound. But consider the following apparently invalid instance:

(1) Hesperus is Phosphorus
(2) Hammurabi believed that Hesperus often rose in the evening
(3) Therefore, Hammurabi believed that 'Phosphorus' often rose in the evening.

If we take 'Hammurabi believed that…often rose in the evening' to serve as the predicate F and 'Hesperus' and 'Phosphorus' to be a *and* b *respectively, this argument appears to be an instance of Leibniz's law. Yet (3) apparently fails to follow from (1) and (2). Hammurabi believed that Hesperus and Phosphorus were two heavenly bodies not one. And he believed that Hesperus did, but that Phosphorus did not rise in the evening.*

We have derived a false conclusion from true premises and an apparently valid law. If that law is really valid, then our argument had better not be a genuine instance of the law. The tempting conclusion, widely accepted, is that we were wrong to construe propositional attitude statements as simple predications. We should not, that is, construe 'Hammurabi believed that…often rose in the evening' to be just a long predicate with the semantic function of attributing some property to the object commonly denoted by 'Hesperus' and 'Phosphorus'. But then the question arises: if attitude reports are not simple predications, what are they? Philosophers have disagreed sharply in their answers. Moreover, their disagreements are intimately connected to a wide range of deep issues about the nature of meaning and reference.

1 Frege on attitude statements

Gottlob Frege was among the first to offer systematic explanations of the form and content of propositional attitude statements (Frege 1892). Central to Frege's treatment of attitude statements is his distinction between sense and reference (see Sense and reference). Frege held that each significant linguistic expression plays two distinct but related semantic roles: it 'denotes' a reference and 'expresses' a sense. For example, the reference of a singular term like a proper name is typically some individual object. A sense, on the other hand, is a way of being given a reference. The sense of a proper name, for example, contains a condition, the unique satisfaction of which by an object *o* is necessary and sufficient to determine *o* as its reference. Perhaps the following captures the sense of 'Phosphorus':

o is Phosphorus just in case *o* is the last celestial object visible in the early morning sky just before sunrise.

The distinction between sense and reference holds not just for proper names but also for sentences. Frege took the reference of a complete declarative sentence to be its truth-value. A declarative sentence is thus a name of sorts - a name for a truth-value. So, for example, the reference of:

(4) Phosphorus can often be seen in the evening sky

is the True, as Frege called it. On the other hand, the sense of a complete declarative sentence is supposed to be a thought, according to Frege. The sense of (4) is the thought that Phosphorus can often be seen in the evening sky.

Frege held that that two expressions may denote the same reference while expressing distinct senses. 'Hesperus' and 'Phosphorus' denote the same object, but differ in sense, from Frege's viewpoint. Something like the

following satisfaction condition arguably captures the sense of ‘Hesperus’:

o is Hesperus just in case *o* is the first celestial object visible in the early evening sky after sunset.

Similarly, although sentence (4) and

(5) Hesperus can often be seen in the evening sky

denote the same reference - namely, the True - they express different thoughts. For the thought that Phosphorus can often be seen in the evening sky is, according to Frege, distinct from the thought that Hesperus can often be seen in the evening sky. One indicator of their distinctness is the possibility that a rational cognizer can simultaneously believe the one, while disbelieving the other. Hammurabi was just such a cognizer.

It is worth enumerating three essential characteristics of Fregean thoughts. First, thoughts are the primary bearers of truth-conditions. The very identity of a thought is constituted by its having the truth-conditions that it has. Sentences, by contrast, have their truth-conditions only derivatively, by being associated with a thought, in virtue of the conventions of a language. Second, thoughts are composite structured entities. A thought is a whole, composed of constituent parts. The parts of thoughts are themselves senses. For example, the thought that Hesperus is often visible in the evening has the sense of ‘Hesperus’ as a constituent part. Third, thoughts are the objects of the propositional attitudes. To believe that Hesperus is often visible in the evening is to stand in a certain relation - the believing relation - to the thought that Hesperus is often visible in the evening. To wonder whether Hesperus is often visible in the evening is to stand in a different relation - the wondering relation - to that same thought.

Frege endorses a principle of compositionality for both sense and reference (see Compositionality). He believes that both the reference and the sense of a complex expression are a function of the references and senses, respectively, of the constituent parts of that sentence (and the way those parts combine to form a whole). Two sentences which differ only by constituents which themselves have the same reference, should have the same truth-value. Similarly, two sentences which differ only by constituents which express the same sense, should themselves express the same thought. Now Frege is convinced that these compositionality principles are nowhere violated. But then the original quandary about attitude sentences remains.

Frege’s way out is to say that despite our initial assessment ‘Hesperus’ as it occurs in (2) and ‘Phosphorus’ as it occurs in (3) do not share a reference. Call the sense and reference of a term as it occurs in direct discourse its ‘customary’ sense and reference. Frege claims that when an expression is embedded within a that-clause, it undergoes a shift in both its sense and its reference. In particular, he holds that obliquely occurring expressions, as he called them, denote not their customary referents, but their customary senses. Moreover, an obliquely occurring term denotes a new sense: what he calls its ‘oblique’ or ‘indirect’ sense. An indirect sense is a mode of presentation not of a term’s customary reference, but of its customary sense. Thus in (2) ‘Hesperus’ refers not to the planet Venus but to the customary sense of ‘Hesperus’. Similarly in (3), ‘Phosphorus’ denotes the customary sense of ‘Phosphorus’. Indeed, a whole sentence undergoes a shift in sense and reference when it is joined with ‘that’ to form a clause. The that-clause in (2), for example, does not denote a truth-value, but the thought customarily expressed by ‘Hesperus often rose in the evening’ when it stands on its own. It denotes, that is, the thought that Hesperus often rose in the evening. And (2) as a whole says that Hammurabi stands in the believing relation to that thought. Similarly, the that-clause in (3) denotes the thought that Phosphorus often rose in the evening. And (3) attributes to Hammurabi the property of believing that thought.

Clearly, if Frege is correct, the invalidity of our original argument does not, after all, violate Leibniz’s law. Since the customary sense of ‘Hesperus’ is not identical to the customary sense of ‘Phosphorus’ our original argument turns out not to involve the substitution of co-referring terms.

2 Referential opacity

Philosophers have sometimes questioned the coherence of Fregean senses. W.V. Quine, for example, has argued that senses and related intensional notions are ‘creatures of darkness’ (Quine 1956). There is no saying, according to Quine, for arbitrary senses *x* and *y*, when *x* and *y* are the same sense and when they are two distinct senses (see Quine, W.V. §8; Radical translation and radical interpretation §§2-3). There can be no entities, he insists, where

there are no determinate criteria of identity. But if senses go, so too must Frege's account of propositional attitude statements.

Quine endorses Frege's negative conclusion that obliquely occurring terms do not play their customary referential roles. He offers, however, a markedly different diagnosis of that failure. Like Frege, Quine believes that where reference happens substitutivity reigns - that is, Leibniz's law holds. But unlike Frege, Quine takes the failure of substitutivity within attitude statements at face value. And he concludes, in effect, that reference cannot be happening within the context of propositional attitude statements or that-clauses generally. That-clauses, he claims, are 'referentially opaque'. Embed a term which elsewhere functions referentially within such a clause and substitution is no longer permissible, not because reference shifts, but because the embedded term is stripped of its referential function. Quine suggests, in fact, that it is a mistake to speak of 'embedding' a referring expression within a that-clause at all. He suggests that an expression like 'believed that Hesperus often rose in the evening' functions rather like a primitive one-place predicate with no 'logically germane' constituent parts. In that case, sentences like (2) are misleadingly spelled. A more revealing spelling would treat this predicate as a single, though very long word somewhat like: 'believed-that-Hesperus-often-rose-in-the-evening'. The presence of the string 'Hesperus' in this very long word is merely an accident of orthography. It would be no more correct to regard 'Hesperus' as a grammatical constituent of this very long word, than it would be to regard the word 'cat' as grammatical constituent of the word 'cattle'.

Referential opacity explains another logical peculiarity of that-clauses, according to Quine. Consider the law of existential generalization:

F(*a*)
Therefore, $(\exists x)\mathrm{F}(x)$

Informally, this scheme says that if *a* has F then there is something or other which has F. Existential generalization allows us to infer from the premise that 'John loves Mary' to the conclusion that 'John loves someone or other'. When we try to apply this evidently valid scheme within the context of a propositional attitude verb, we are led into apparent contradiction. Consider the following sentence:

(6) The president suspects that someone is a spy.

As it stands, (6) is subject to two different readings. On one reading, (6) says that the president 'suspects true', as we might put it, a certain statement or proposition - the statement or proposition that spying sometimes happens. This reading has been variously called the '*de dicto*', 'notional', or 'referentially opaque' reading (see De re/de dicto). There is a second reading of (6) which attributes to the president not just the generalized suspicion that spying sometimes happens, but the state of being 'suspicious of' some person or other. We might paraphrase this reading of (6) by:

(6b) The president suspects someone of being a spy

or by:

(6c) There is someone whom the president suspects of being a spy.

This reading is variously called the '*de re*', 'relational', or 'referentially transparent' reading. The two readings are not generally equivalent. It is possible to suspect that spying happens even when one has no suspicions about any particular person. The ambiguity in sentences like (6) is sometimes traced to an ambiguity of quantifier scope. On the so-called *de dicto* or opaque reading of (6), the quantifier has narrow scope relative to 'believes'. On the so-called *de re* or transparent reading, the quantifier has wide scope relative to 'believes'. As a first pass, we might represent the *de dicto* reading by (6d) and the *de re* reading by (6e):

(6d) The president suspects that $(\exists x)(x \text{ is a spy})$
(6e) $(\exists x)(\text{The president suspects that } x \text{ is a spy})$.

Quine has argued that constructions like (6e), in which a quantifier sitting outside the scope of the attitude verb 'reaches in' to bind a variable that lies within the scope of that attitude verb, are deeply problematic. We cannot,

he claims, 'quantify into' attitude contexts (Quine 1956). Or to put it in slightly different terms, propositional attitude verbs appear to block the interior reach of exterior quantifiers.

Suppose that the president has observed Stanley P. Young, a certain low-level White House aide, behaving in a rather furtive manner. He says with great conviction to the chief of White House security, 'Stanley P. Young is a spy.' That seems a sufficient basis for attributing to the president the belief that Stanley P. Young is a spy and thus a sufficient basis for taking this to be true:

(7) The president believes that Stanley P. Young is a spy.

If we construe 'The president believes…is a spy' as a complex predicate, then from (7) and the law of Existential Generalization, we should be able to infer:

(8) $(\exists x)(\text{The president believes that } x \text{ is a spy})$.

There may be a number people whom the president believes to be spies. Stanley P. Young is one such person. $(8')$ below would also seem to follow:

$(8')$ $(\exists x)(x = \text{Stanley P. Young \& the president believe that } x \text{ is a spy})$.

Now suppose that the president is subsequently introduced to one James Q. Money, a generous contributor to progressive causes and a man of stellar reputation. The president trusts Mr Money. When asked whether Money is a spy, the president denies even the possibility. That denial is grounds for inferring:

(9) The president believes that James Q. Money is not a spy.

From (9) and Existential Generalization we can infer:

(10) $(\exists x)(\text{The president believes that } x \text{ is not a spy})$.
$(10')$ $(\exists x)(x = \text{James Q. Money \& the president believe that } x \text{ is not a spy})$.

But unbeknownst to the president, James Q. Money leads a double life. He is none other than Stanley P. Young. Does the president believe or not believe James Q. Money, that is, Stanley P. Young, to be a spy? Intuition pulls in opposite directions. Since James Q. Money just is Stanley P. Young, we should, by Leibniz's law, be able to substitute 'Young' for 'Money' in $(10')$ without change of truth-value. Since this substitution happens outside the that-clause, it should be unaffected by the logical peculiarities of such clauses. Yet substitution yields:

$(10'')$ $(\exists x)(x = \text{Stanley P. Young \& the president believe that } x \text{ is not a spy})$.

Examples $(10'')$ and $(8')$ are of dubious consistency. No one can both be and not be a spy. So how can anyone consistently both believe a person to be a spy and believe that very person not to be a spy?

The answer lies in referential opacity. Because (7) and (9) are opaque, they do not ascribe to the president incompatible relations to Money, that is, Young. Indeed, opaquely construed, the Quinean insists, neither (7) nor (9) relates the president to Money, that is, Young at all. Recall again the Quinean view that when opaque contexts are perspicuously spelled the illusion that they contain referring expressions as proper constituents will have been dispelled. Indeed, opacity renders quantified sentences like $(10')$ and $(10'')$ utterly nonsensical. For proper respelling reveals that there is no genuine occurrence of an interior variable for the exterior quantifier to bind. An analogy with quotation - which Quine takes to be the referentially opaque context *par excellence* - makes the reason clear. Consider:

(11) '*x* is a spy' is an open sentence.

Enclosing an expression within quotation marks seals that expression off from the reach of external quantifiers. The quantifier below does not bind the quoted variable:

(12) (∃*x*)('*x* is a spy' is an open sentence).

What occurs within the quotation marks is really not a variable *in use*. It is rather a variable *being mentioned* (see

Use/mention distinction and quotation). Similarly, though what occurs in (10′) and (10″) bears a certain orthographic resemblance to a variable in use, it is not the real thing. For that reason we can no more quantify into propositional attitude contexts, Quine insists, than we can quantify into the context of quotation.

Quine's approach promises a way out of the threatened contradiction, but only by doing great violence to a number of potent intuitions. It seems frankly incredible that putatively referring terms embedded within a that-clause are mere grammatical illusions. Further, if propositional attitude statements lack logically germane constituents, there will be no accounting for certain systematic commonalities and differences among such statements. Compare and contrast, for example, (7) and (9) above with (13) and (14) below:

(13) The First Lady *doubts that* Young is a spy
(14) The vice-president *wonders whether* Young is a spy.

Example (13) seems to say that the First Lady doubts what the president believes, while (14) says that the vice-president has questions about what the First Lady and the president disagree about. Moreover, the president's belief, the First Lady's assurance and the vice-president's questions seem all to be about one and the same individual. Quine's approach abandons these intuitive judgments.

Quine is well aware of these costs. He believes, however, that we must pay the cost if we are to keep the creatures of darkness - Fregean senses and other intensional entities - at bay (see Intensional entities).

3 Innocence regained?

Donald Davidson has argued that if we could but regain our pre-Fregean semantic innocence:

> it would seem to us plainly incredible that the words 'The earth moves' uttered after the words 'Galileo said that' mean anything different, or refer to anything else, than is their wont when they come in other environments.
>
> (Davidson 1969: 172)

If Davidson is right then we can account for the logical peculiarities of attitude statements without positing Fregean reference shifts. Nor, if he is right, need we allow that otherwise referring terms are stripped of their referential functions when they occur in attitude contexts. Indeed, against Quine, Davidson holds that unless we have already been forced to introduce Fregean senses for other reasons, the peculiarities of attitude contexts provide no additional pressures to posit such entities. So if Davidson is right, Quine's drastic departures are not needed to keep intensions at bay.

Davidson defends what he calls a 'paratactic analysis' of the logical forms of indirect discourse, though his approach can be extended fairly directly to attitude ascriptions. Davidson's central claim is that a sentence like:

(15) Galileo said that the earth moves

is really a parataxis of two sentences. The first sentence of the parataxis in (15) ends with the word 'that'; the second starts with 'the earth'. By adding a bit of punctuation, we can represent (15) in a more perspicuous manner as:

(16) Galileo said that. The earth moves.

Call the first sentence the attribution sentence and the second the content sentence. In the attribution sentence of (16), the 'that' is a demonstrative pronoun which refers (on an occasion) to an utterance of the second sentence of (16).

Sentence (16) will be true, according to Davidson, just in case some utterance of Galileo's makes Galileo and the utterer of (16) 'samesayers'. Suppose that Galileo utters (17) and Smith utters (18):

(17) Eppur si muove.
(18) The earth moves.

In some sense, Galileo and Smith say the same thing. Moreover, if Smith utters (18) and Galileo utters (17) then

'the earth' in Smith's mouth and 'Eppur' in Galileo's mouth have the same reference.

Suppose that Smith wants to attribute Galileo's statement to Galileo. He can do so simply by saying the same thing as Galileo and then saying that he has just done so - as in the following scenario:

(19) Galileo: Eppur si muove.
(20) Smith: The earth moves. Galileo said that (too).

Here we have Galileo saying, in Italian, that the earth moves. We have Smith saying the same thing in English. And then we have Smith ascribing such a statement to Galileo. He does so by making a statement that turns himself and Galileo into samesayers (to use Davidson's phrase) and then stating that he has just done so. As matters stand, it remains unclear until Smith utters the second sentence of (20) just what the point of his initial utterance may be. But we can rectify that by reversing the order of the sentences as follows:

(21) Galileo said that. → The earth moves.

The arrow in (21) should be understood as a demonstration accompanying the demonstrative pronoun 'that'. The demonstrative refers to Smith's second utterance - the one by which Smith purports to turn himself and Galileo into samesayers. While Smith 'refers' to his own utterance, he implicitly 'quantifies over' Galileo's utterances. Smith says, in effect, that the demonstrated utterance of his and 'some utterance or other' of Galileo's make himself and Galileo samesayers.

Davidson's account yields a relatively straightforward explanation of the invalidity of inferences like the following:

(22) Galileo said that. → The earth moves.
(23) The earth is the third planet from the sun.
(24) Galileo said that. → The third planet from the sun moves.

There is no logical connection between the effect of substitution on the content sentence and the truth-values of the two attribution sentences. As Davidson puts it:

> There is no reason to predict, on grounds of form alone, any *particular* effect on the truth of [the attribution sentence] from a change in [the content sentence]. On the other hand, if the [content sentence] had been different in any way at all, [the attribution sentence] *might* have had a different truth-value, for the reference of the 'that' would have been changed.
>
> (Davidson 1969: 172)

Though Davidson's central idea is quite ingenious, there are both syntactic and semantic grounds for scepticism. For example, content clauses are not generally introduced by demonstratives. Neither 'whether' in 'Galileo wondered whether the earth moves' nor 'for… to' in 'I would prefer for you to leave' can plausibly be analysed as overt demonstratives. Moreover, demonstratives cannot in general be deleted, but the 'that' in '… said that… ' can. Compare the following:

(25) Davidson saw that man over there.
(26) Davidson said that the paratactic analysis is true.
(27) ?Davidson saw man over there.
(28) Davidson said the paratactic analysis is true.

It is also difficult to see how to extend the paratactic analysis to *de re* ascriptions. Consider (29):

(29) Every philosopher believes that he is wise.

Example (29) says, in effect, that every philosopher has a high opinion of himself. But if we interpret (29) along Davidsonian lines as:

(30) Every philosopher believes that. He is wise.

we get something rather different.

Finally it is clear that we need to know more about the samesaying relation. If the paratactic analysis is to overcome the need to introduce Fregean senses and the like, then samesaying cannot just be a matter of expressing the same Fregean sense. Davidson owes us an account of samesaying which eschews senses and other intensional entities altogether. Davidson is fully aware of this debt and labours mightily to pay it (Davidson 1969).

4 Structured complexes

A class of theories which has recently gained favour with a number of philosophers is what might be called the structured complex approach (see Intensional logic §5). Advocates of such theories maintain that attitude verbs express relations between agents and complex hierarchically structured entities of one sort or another. The core idea dates back to Carnap (1947). It has resurfaced, much modified, in Cresswell (1984), Segal (1989), Richard (1990), Higginbotham (1991) and Larson and Ludlow (1993). Different versions of this approach posit different structured complexes. Carnap posited hierarchically structured intensions. Others pair semantic values with something else: sometimes a sentence, sometimes a description of a sentence, sometimes a structured intension. Larson and Ludlow, for example, hold that that-clauses specify Interpreted Logical Forms (ILFs). An ILF is a kind of product of a phrase structure tree for a sentence and the sequence of semantic values for the semantically valued constituents of that sentence. On their approach, the sentence:

(31) Pierre admires London

will be associated with the ILF in Figure 1:

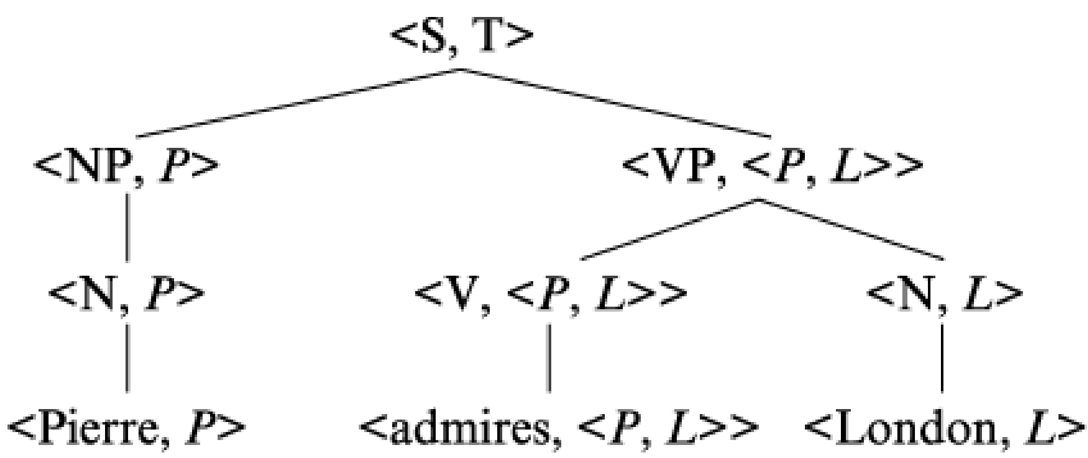

Figure 1

We need not worry about the exact formation rules that generate this ILF. The crucial point is that each node in this tree is labelled by a pair whose left member is either a lexical item (at the bottom-most nodes) or a phrase marker (at all other nodes) and whose right member is a semantic value. For example, the pair $\langle \text{Pierre}, P\rangle$ is the pair whose left member is the word 'Pierre' and whose right member is the reference of 'Pierre' (namely, Pierre himself). The pair $\langle \text{admires}, \langle P,\ L\rangle\rangle$ has left member 'admires' and a right member consisting of a pair whose members are Pierre and London. Such trees are intended to represent a sequence of semantic values and the order in which those semantic values are associated with the expressions whose values they are. Because lexical items (words themselves), and not just phrase makers, are constituents of ILFs, the following two sentences will have distinct ILFs:

(32) Hesperus rises in the evening.
(33) Phosphorus rises in the evening.

Nonetheless, (32) and (33) have, according to Larson and Ludlow, the same semantic content. That is, (32) and (33) have formally distinct but semantically equivalent ILFs. Armed with the notion of formally distinct but semantically equivalent ILFs, Larson and Ludlow are able to explain how it is possible for attitude statements like our original (2) and (3) to differ in truth-value. The thought is that an agent who stands in the believing relation to

the ILF of ‘Hesperus rises in the evening’ need not *ipso facto* stand in the believing relation to the ILF of ‘Phosphorus rises in the evening.’ Yet one who believes that Hesperus rises believes the very same semantic content as one who believes that Phosphorus rises.

Notice that Larson and Ludlow walk the middle ground between Davidson and Frege. Their approach is ontologically conservative like Davidson’s. For the structural descriptions and semantic values out of which ILFs are composed must already be introduced in to our ontology to account for the semantic and syntactic character of sentences other than those about propositional attitudes. But their explanation of failures of substitutivity is analogous to Frege’s own. They too appeal to the fact that, at least in attitude contexts, more is relevant to substitutivity than mere co-reference. That more is, however, not anything semantic. So we are not required, merely because of the peculiarities propositional attitude statements, to posit for each referring expression a second semantic role over and above its role of standing for a referent.

5 Hidden indexicality

Consider the following three theses:

(a) *The Direct Reference Thesis.* The sole semantic role of a proper name is to stand for its bearer.
(b) *Semantic Innocence.* A name plays the same semantic role when embedded within a that-clause as it plays when it occurs outside a that-clause.
(c) *The Fregean Intuition.* Propositional attitude statements which differ only by co-referring proper names may differ in truth-value.

Each of these theses has considerable independent plausibility. But they are not obviously consistent. Frege was moved to abandon both thesis (a) and (b) because he thought they could not be reconciled with (c) (see Proper names §5). More recently, Nathan Salmon (1986) has abandoned (c) out of a commitment to (a) and (b). He has insisted that it is merely a pragmatically generated illusion that sentences like (2) and (3) have different truth-values. He claims that strictly, literally speaking, one who believes that Hesperus rises *ipso facto* believes that Phosphorus rises. It is just that it is conversationally misleading to talk that way. That is because belief is not a two place relation between a believer and a proposition, but a three place relation between a believer, a proposition and what we might call a ‘way of believing’ that proposition. Propositions are never believed *simpliciter*, but always in some way or other, under some guise or other. Moreover, Salmon insists, a rational cognizer can believe a given proposition under one guise while failing to believe it under a different guise. But the crucial further point is that nothing in an attitude ascription semantically specifies the guise under which the proposition named by the that-clause is supposed to be believed. The guise simply does not enter into the strict literal truth-conditions of an attitude statement. Nonetheless, Salmon suggests, we can pragmatically suggest something about the guise, by using one expression rather than another semantically equivalent one in making an attribution. If we use ‘Hesperus’ we suggest something different about the guise than we would if were to use ‘Phosphorus’. That is why it is pragmatically misleading to use ‘Hesperus’ and ‘Phosphorus’ interchangeably in making attitude ascriptions.

By contrast, hidden indexicalists insist on all of our principles, and offer a strategy, with several variants, for reconciling them (see Schiffer 1979; Crimmins and Perry 1989; Richard 1990; Crimmins 1992). Proponents of the hidden indexical approach generally agree with the view that belief is a three-place, rather than merely a two-place relation. They even agree that that-clauses which differ only by co-referring proper names must refer to the same (singular) proposition. But they insist that attitude ascriptions do not just pragmatically suggest information about the guise under which the specified proposition is believed. Information about the guise is part of what is strictly, literally said by an attitude ascription. That is why, against Salmon, the Fregean intuition is here to stay.

Yet, given the assumption of semantic innocence, how could that-clauses which differ only by corresponding co-referring proper names specify distinct ways of believing? The answer, according to the hidden indexicalist, is that there is more to an attitude statement than meets either the eye or the ear. Attitude reports contain hidden or unarticulated indexical constituents. These unarticulated constituents are not reflected in the surface grammatical structure of the sentence, but in a context of utterance they somehow refer to a way of believing. Consequently, attitude sentences, in context, manage to express propositions with more explicit constituents than they themselves have. Such sentences can be compared, the hidden indexicalist says, to sentences like the following in which one term of a relation is suppressed, but can be supplied, in context, by competent producers and consumers:

It is raining.	(Where?)
I am ready.	(For what?)
That is tall.	(For a what?)
Smith believes that p.	(How?)

When one utters, ‘It is raining’ on a certain occasion, one strictly, literally says that it is raining in a certain place - typically the place of utterance - even though no explicit constituent of one’s utterance refers to that place. Just so, the hidden indexicalist maintains, when one utters a belief report on an occasion, one strictly, literally says that a certain proposition is believed in a certain way. And one does so even though no explicit constituent of one’s utterances refers to the way of believing. Now the crucial further claim has to be that although ‘Hesperus’ and ‘Phosphorus’ have the same semantic value and function innocently, even in that-clauses, nonetheless, exchanging one for the other can affect the way an unarticulated constituent gets hooked up to a reference as a function of context. And that can explain why they are not freely substitutable one for another.

Clearly, the hidden indexicalist owes us a detailed account of these matters. We need to be told what a way of believing is. We need to know how specified ways of believing vary as a function of facts about context and facts about articulated constituents. Fortunately, the best advocates of this approach have gone a long way towards answering such questions.

Propositional attitudes

Examples of propositional attitudes include the belief that snow is white, the hope that Mt Rosea is twelve miles high, the desire that there should be snow at Christmas, the intention to go to the snow tomorrow, and the fear that one shall be killed in an avalanche. As these examples show, we can distinguish the kind of attitude - belief, desire, intention, fear and so on - from the content of the attitude - that snow is white, that there will be snow at Christmas, to go to the snow, and so forth. The term 'propositional attitudes' comes from Bertrand Russell and derives from the fact that we can think of the content of an attitude as the proposition the attitude is towards. It can be typically captured by a sentence prefixed by 'that', though sometimes at the cost of a certain linguistic awkwardness: it is more natural, for example, to talk of the intention to go to the snow rather than the intention that one go to the snow. The most frequently discussed kinds of propositional attitudes are belief, desire and intention, but there are countless others: hopes, fears, wishes, regrets, and so on.

Some sentences which contain the verbs of propositional attitude - believes, desires, intends, and so on - do not make ascriptions of propositional attitudes. For example: 'Wendy believes me', 'John fears this dog', and 'He intends no harm'. However, while these sentences are not, as they stand, ascriptions of propositional attitudes, it is arguable - though not all philosophers agree - that they can always be analysed as propositional attitude ascriptions. So, for example, Wendy believes me just in case there is some p such that Wendy believes that p because I tell her that p; John fears this dog just in case there is some X such that John fears that this dog will do X and so on.

Discussions of propositional attitudes typically focus on belief and desire, and, sometimes, intention, because of the central roles these attitudes play in the explanation of rational behaviour. For example: Mary's visit to the supermarket is explained by her desire to purchase some groceries, and her belief that she can purchase groceries at the supermarket; Bill's flicking the switch is explained by his desire to illuminate the room, and his belief that he can illuminate the room by flicking the switch; and so on. It is plausible - though not uncontroversial - to hold that rational behaviour can always be explained as the outcome of a suitable belief together with a suitable desire.

Some philosophers (examples are Grice and Schiffer) have used the propositional attitudes to explain facts about meaning. They hold that the meanings of sentences somehow derive from the contents of relevantly related beliefs and intentions. Roughly, what I mean by a sentence S is captured by the content of, say, the belief that I express by saying S.

One fundamental question which divides philosophers turns on the ontological status of the propositional attitudes and of their contents. It is clear that we make heavy use of propositional attitude ascriptions in explaining and interpreting the actions of ourselves and others. But should we think that in producing such ascriptions, we attempt to speak the truth - that is should we think that propositional attitude ascriptions are truth-apt - or should we see some other purpose, such as dramatic projection, in this usage? Or, even more radically, should we think that there is nothing but error and confusion - exposed by modern science and neurophysiology - in propositional attitude talk?

1 Elementary distinctions

Propositional attitude ascriptions standardly take the form 'X Fs that p', where 'X' denotes the subject of the attitude, 'F' is a verb of propositional attitude, and 'that p' gives the content of the attitude. So, for example, in the sentence 'John believes that snow is white', 'John' denotes the subject of the attitude, 'believes' is the verb of propositional attitude, and 'that snow is white' gives the content of the attitude.

Taking the form of these ascriptions at face value, it is natural to suggest that a propositional attitude ascription of the form 'X Fs that p' is true just in case X is in a propositional attitude state of type F - a F-state - which has the content that p. So, for example, 'John believes that snow is white' is true just in case John is in a belief-state which has the content that snow is white; 'Mary hopes that Sheila is happy' is true just in case Mary is in a hope-state which has the content that Sheila is happy; and so on. More generally, it is natural to divide a discussion of propositional attitudes into two parts: one part which focuses on the nature of propositional attitude states - the difference between hoping, fearing, believing, wishing, and so on - and one part which focuses on propositional

attitude contents - the difference between believing that snow is white, believing that snow is grey, believing that snow falls at night, and so forth.

It is plausible to think that belief and desire are the basic exemplars of two quite different kinds of attitudes, with characteristically different directions of fit. On the one hand, there are attitudes, like belief, which aim to fit the world - and, hence, which are important for theories of truth, impact of evidence, credence, and so on. And, on the other hand, there are attitudes, like desire, which aim to have the world fit them - and, hence, which are important for theories of value, virtue, wellbeing, and so on. Some philosophers think that all of the propositional attitudes can be explained in terms of beliefs and desires; they think that the apparent multiplicity of kinds of propositional attitudes is merely apparent - hope, for example, is a kind of desire about the future - and that direction of fit is the only fundamental dimension which needs to be considered in classifying the propositional attitudes.

2 Propositional attitude states

If beliefs, desires, intentions, and the like, are states of subjects, what kind of states are they? A plausible view is that they are functional states - states defined or determined or specified by their functional roles. According to functionalist theories, propositional attitude states are fully determined by their causal relations to one another, to perceptual inputs, and to behavioural outputs (see Functionalism). So, for example, what makes a certain state a state of believing that there are *Cheerios* in the cupboard turns on its being typically caused by packets of *Cheerios*, or more precisely, on the role it plays in the processing of perceptual input - say, guessing the contents of that visually presented cardboard box in the cupboard; on the way it leads to other states - say, believing that there is cereal in the cupboard; and on the way it combines with hunger and desire to eat some cereal to produce behaviour that leads to eating.

There are, however, two different ways of thinking of functional states: as role states or as realizer states. Realizer states are first-order states that stand in the functional roles; they are the particular states which play the roles. Role states are second-order states: the state of being in, some first-order state playing a certain kind of functional role. So, in the case of belief, say, there is the first-order realizer state (the state which actually fills the belief role - the state which mediates between perceptual inputs and behavioural responses in the way distinctive of belief); and there is the second-order role state (the state of being in some state or other which realizes the belief role - the state of being in a state that mediates in the way distinctive of belief between perceptual inputs and behavioural outputs). Should we think of belief in particular and propositional attitudes in general as realizer states or as role states?

The obvious reason for holding that propositional attitude states are realizer states rather than role states is that the propositional attitudes are centrally involved in the causation of behaviour, and it is the realizer states but not the role states that are centrally involved in the causation of behaviour. It is, for instance, the particular internal state which fills the role we associate with believing that snow is white that causes the behaviour distinctive of this belief - for example, uttering the words ‘Snow is white’.

There are, however, also considerations that point the other way, that favour holding, for example, that my belief that snow is white is the role state which is realized by some particular internal state of mine. In particular, it seems that taking propositional attitude states to be role states allows one to formulate psychological generalizations which one would miss if one took propositional attitudes to be realizer states. Consider, for example, the generalization: everyone who believes the world is going to end in ten minutes gets anxious. Suppose that there are actually M realizer states for the belief: $N_1, N_2, \ldots, N_M$. These states, we may suppose, each play the appropriate causally intermediate roles distinctive of the belief that the world is going to end in ten minutes in somewhat the way that transistors and valves, despite being very different, can both play the roles distinctive of amplification. If the belief state is identical with the realizer states, then the only way to generalize is to treat the realizer state as a disjunction $N_1 \vee N_2 \vee \ldots \vee N_M$. But this disjunction is ugly, and not suitable for the formulation of psychological law. The generalization can be saved by recasting it as one about role states, but then the only way the initial generalization can be a generalization about the belief that the world is going to end in ten minutes is if that belief is a role state. The general point is that the patterns we capture in psychological generalizations relate to role states, so the cost of holding that psychological states are realizer states is that psychological generalizations cease to relate psychological states.

Whether propositional attitude states are best thought of as role states or realizer states, it has seemed plausible to many philosophers that the realizer states are physical states of the brain - or, at any rate, states which supervene upon physical states of the brain (see Mind, identity theory of; Supervenience of the mental). This is put forward as a plausible scientific hypothesis. Only in the brain are there states of sufficient complexity to play the needed roles. It is, though, allowed as a logical possibility that there could have been other (perhaps even non-physical) realizer states which filled the same role.

Some philosophers, however, have worried about whether neural states could be the kinds of things which can be adverted to, even *inter alia*, in the explanation of rational action. The connections between neural states are merely causal, they argue - playing out the universal laws of physics, or of neuroscience - whereas the connections between states of propositional attitude are rational (and serve to rationalize behaviour). One belief makes another the rational one to have; what one believes and desires may make one action more rational than another; and so on (see Reasons and causes).

However, there are serious problems with this sort of objection. Would the cause of rationality be better served by having the attitudes occurring at random? And surely a decent account of the propositional attitudes places them in the physical world - they are not otherworldly mysteries - and given this, there seems little alternative to placing them in the brain: we know that the propositional attitudes play complex causal roles in the production of our behaviour, and only the brain has states capable of the needed complexity. Finally, it is unclear why one might suppose that functionally defined states cannot have the rationalizing properties which are alleged to vanish from the scientific picture (see Loar 1981 for further discussion).

3 Propositional attitude contents

The contents of propositional attitudes are propositions. That much is simply a matter of definition. But what are propositions? There are at least the following contenders: (1) collections of circumstances of evaluation, such as collections of possible worlds; (2) syntactic entities, such as interpreted sentences in natural language; (3) set-theoretic structures, such as Fregean thoughts (see Frege §§3-4). Only some of the strengths and weaknesses of these different approaches can be examined here (see Propositions, sentences and statements).

(1) One important virtue of the theory that propositions are collections of possible worlds - that is, collections of complete ways that things could be (see Semantics, possible worlds) - is that it directly captures the intuition that propositions involve a sorting among ways that things could be. For example, in believing that snow is white, one believes that the actual complete way that things are is among those complete ways that things could be in which snow is white; in desiring that snow falls at Christmas, one desires that the actual complete way that things are is among those in which snow falls at Christmas; and so on.

Perhaps the most important drawback of this theory is that its most plausible formulations seem to give the wrong results for attitudes with logically equivalent contents. For example, it entails that the belief that there are husbands is identical to the belief that there are wives. Because ‘There are wives’ is logically equivalent to ‘There are husbands’, the set of worlds where there are wives is one and the same as the set of worlds where there are husbands. Likewise, it makes the desire to prove that two and two are four identical to the desire to prove that arithmetic is not decidable, and the intention to draw an equiangular triangle identical to the intention to draw an equilateral triangle. As the objection is commonly put, the possible worlds theory delivers objects of the attitudes that are insufficiently fine grained - there are more distinct attitude contents than it allows.

In addition, there is a complication which needs to be addressed. Consider, for example, my belief that I am cold, or your belief that you are spilling sugar on the floor of the supermarket. These attitudes *de se* (about oneself), as they are called, need to be thought of as involving a sorting among ways that things might be centred on the subject - me, here and now, as it could be, rather than of complete ways things might be (see Demonstratives and indexicals; Content, indexical).

(2) One important virtue of the theory that propositions are syntactic entities - that is entities with sentence-like structure - is that it provides objects to discriminate between attitude contents which, as we have just seen, the possible worlds theory is unable to discriminate. For example, the sentence ‘There are husbands’ is distinct from the sentence ‘There are wives’; and the theory can exploit this fact to distinguish the belief that there are husbands from the belief that there are wives. They are attitudes to different though equivalent sentences.

However, if the sentences are thought of as being in a natural language, this advantage is purchased at a price; it provides distinctions where it is plausible that there are none. Consider, for example, our practice of translating and interpreting those who speak different languages. Clearly, 'Snow is white' and 'La neige est blanche' are distinct sentences - but surely we are not thereby obliged to say that it is impossible for a monolingual French speaker to believe that snow is white? Consider, too, the belief that p, and the belief that p and p. There is at least some temptation to think that these are not distinct beliefs.

One response is to argue that the sentences in question do not belong to natural languages but rather to a language of thought - that is, to a neural system of information or information storage which is supposed to have syntactic structure, and that this is something we all share (and share with animals like dogs that lack public language but do seem to have propositional attitudes) (see Language of thought). One difficulty with this suggestion is that it seems wrong that a mere analysis of propositional attitudes will commit us to the existence of a language of thought, a substantive view about our neural natures. It seems to be an empirical question, for example, whether mental representation is language-like or map-like (see Belief §3), but the language of thought hypothesis commits us in advance to the former alternative.

(3) One important virtue of the theory that propositions are set-theoretic structures - that is entities whose basic structure is described by set theory (see Set theory) - is that it promises to cope with the difficulties mentioned above for the syntactic and possible worlds accounts. However, before we can see why this is so, we need to give some explanation of the theory.

Consider, for example, the sentence 'London is pretty'. A natural thought is that the proposition expressed by this sentence is somehow made up of the city of London (or some way of thinking about it) and the property of being pretty (or some way of thinking about the property of being pretty). More generally, the theory holds that propositions are composed from constituents which are somehow put together in an orderly (set-theoretic) fashion. The constituents in question include: individual objects (and perhaps modes of presentation thereof), which correspond to proper names and other singular terms; properties, which correspond to predicates; functions, which correspond to sentential operators (such as 'and' and 'possibly'), and so on.

This view has the resources to discriminate between the belief that there are husbands and the belief that there are wives, one of the examples that gave the possible worlds approach trouble. Roughly, the first has in its propositional object women and the property of being married to men, whereas the second has men and the property of being married to women. The view also has the resources to identify the propositions expressed by the sentences 'Snow is white' and 'La neige est blanche' and so allow that speakers of different languages can share beliefs, one of the examples that gave the sentential theory trouble. Although the words differ, the objects and properties they stand for are the same and hence the propositions thought of as constructed from them are the same. However, the theory in its typical form has to distinguish between the belief that p, and the belief that p and p - the propositional object of the second is special in involving the operation of conjunction - and this is not clearly desirable.

Another problem with set-theoretic approaches is that they involve various kinds of 'disreputable entities' - intensional properties, modes of presentation ('Fregean senses'), perhaps even set-theoretic functions - which many philosophers would like to exclude from their theories of the attitudes (see Intensional entities). They worry about how these entities can be tied to propositional attitudes, especially if these attitudes are thought of functionally. What causal role can intensional properties or sets, for instance, play? True, this is part of a hard question that arises for any account of the attitudes. We have been discussing competing views about what the objects of the attitudes are. But there is also the question as to how a given propositional attitude state gets attached to the proposition it is attached to; the question of what makes it true, for example, that a certain state is the belief that snow is white rather than that grass is green. We will set this important question aside except to remark that the set theoretic view of the nature of the attitudes is often thought to be especially ill placed to tackle it.

Plainly, there is much more to be said about each of the options discussed here (and about other options as well). The important point is that there are many dimensions to propositional content, and that it is far from easy to provide a theory which scores well on every dimension. A good theory of propositional content should have all of

the following features:

(1) it should be naturalistically respectable - that is compatible with the outlook of natural science;
(2) it should capture the normative dimensions of propositional content;
(3) it should allow a fine-grained discrimination of the contents of propositional attitudes (logical equivalence is not sufficient for identity);
(4) it should not tie the possession of propositional attitudes too tightly to particular languages (for example, it should allow that the same attitudes can be had by creatures which do not share a language - and, indeed, that attitudes can be possessed by creatures which do not speak any language at all);
(5) it should make it clear how states which possess that kind of propositional content can play a role in the production of (rational) action.

4 Propositional attitude ‘aboutness’

Many philosophers have been puzzled by the various ways and senses in which propositional attitudes can be about particular objects and kinds of objects (see Intentionality). Think, for example, of the beliefs which one might have about Aristotle, about Einstein, about President Clinton, about Zeus, about Mickey Mouse, about Meinong’s round square, about gold, about phlogiston, about π, and about the greatest prime number. There are several different issues which can arise here.

One issue concerns the existence of the objects and kinds of objects which are the focus of the attitudes. There is a sense of ‘about’ in which one cannot have attitudes about an object (or kind of object) which does not exist - so that, for example, in this sense, one cannot have beliefs, hopes, fears, desires, and so on, about Zeus, the round square, the greatest prime number, Mickey Mouse and phlogiston, though one can have these attitudes about President Clinton and gold. (The cases of entirely past objects - Aristotle and Einstein - and numbers - π- raise other controversial questions about existence which cannot be taken up here.) This sense of ‘about’ is relational: the point parallels the impossibility of parking near the round square, shaking hands with Zeus, or adding three to the greatest prime number.

Another issue concerns the nature of the connection which obtains between subjects and those existent objects and kinds of objects which are the focus of given attitudes. If one is not appropriately connected to an object, then - in this sense - one cannot have attitudes about it. Suppose, for example, that by an extraordinary coincidence there is a planet somewhere in the universe whose history is exactly described by Tolkien’s *Lord of the Rings*. Even though there is some sense in which Tolkien’s work is true of this planet, nonetheless, the work is not about the planet (in the sense currently at issue). The reason is that the planet played no role at all in the causal history of the book. When, for example, one believes that Hawking is a genius, what makes it the case that one’s belief is about Hawking is, very likely, at least in part, that there are chains of usage of the word ‘Hawking’ which are appropriately connected to that theoretical physicist. When I believe that that tree outside my window is shedding its leaves, what makes it a belief about that tree is, at least in part, the causal processes involving electromagnetic radiation passing between the tree and my retina which are involved in the formation of my belief. In general, it seems plausible to think that some kind of causal connection is required for these kinds of attitudes about particular objects.

However, while it is clearly correct to say that there is a sense in which the aboutness of propositional attitudes is a matter of standing in a relation, an appropriate causal connection on most views, it is also clear that there is another sense of ‘about’ which cannot be analysed in this way. In some sense we can have beliefs and desires about non-existent objects - for example, some people desire to find the fountain of youth, some believe that Meinong’s round square is round, some hoped that Zeus would smite their enemies with a thunderbolt, and so on. It seems clear that those who, for example, hoped that Zeus would smite their enemies have a hope ‘about’ Zeus despite not standing in a relation, causal or otherwise, to Zeus.

How then should this final, non-relational, non-causal, sense of ‘about’ be analysed? Many alternatives present themselves. One might appeal to counterfactuals: attitudes ‘about Zeus’ are attitudes about something which does not exist, but which might have existed; attitudes ‘about phlogiston’ are attitudes about something which does not exist but which might have existed; and so on. One might hold that this sense of ‘about’ is only used in loose speech, and can be banished or paraphrased away in serious philosophical discourse: attitudes ‘about Zeus’ are

really attitudes which focus on certain myths and stories; attitudes ‘about phlogiston’ are really attitudes about a false chemical theory; and so on. One might try various other options as well. The issue is too difficult to discuss adequately here: the important point is that there is at least a loose sense in which there is ‘existentially neutral’ content, that is, content which does not commit one to the existence in the actual world of the particular individuals and kinds to which the content does give apparent commitment.

There is also an important distinction between two different kinds of content: broad content and narrow content. Roughly speaking, narrow content is purely a matter of what goes on inside the head of a subject of propositional attitude states, whereas broad content is in part a matter of how things are in the world outside the head. More exactly, if two subjects are intrinsic duplicates who live under the same laws of nature and belong to the same kinds, then their attitudes are exactly alike in narrow content but may differ in broad content (see Content: wide and narrow).

Once upon a time it was more or less taken for granted that the content of belief, for example, was narrow. How things are outside the head obviously affects whether your beliefs are true or false - your belief that London is pretty can only be true if London itself is pretty - but what you believe is a matter of how you are. But in fact the belief that London is pretty is a belief with broad content. I cannot believe that London, the capital city of England, is pretty unless I am appropriately causally connected to London, and that concerns how things are outside my head. Imagine that the universe is symmetrical, so that there is a region - call it Twin Earth - which is qualitatively identical to our own at all times. It will contain a city called ‘London’ and a twin of me. This twin will be an intrinsic duplicate of me and will produce the sentence ‘London is pretty’ as expressing what he believes. Nevertheless, his belief (and his sentence) will have a different content from mine. It will be about Twin London rather than about London, and will be true just if Twin London, rather than, London is pretty.

5 Defining propositional attitudes

The characterization of propositional attitudes in §2 was very rough, and leaves room for the thought that functionalism involves circularity of definition. We in effect identified the behaviour beliefs cause as behaviour that tends to realize desires, and this bit of inter-defining looks rather like circularity. However, the characterization can be improved in a way which makes it clear that this is not so - and, as an added bonus, also makes clear just what would be involved in the denial of the existence of propositional attitudes. The secret is to take the general account of the definition of theoretical terms provided by David Lewis and apply it to the propositional attitudes.

Roughly, the idea is to collect together a class of sentences involving the verbs of propositional attitude and treat this class as a simultaneous definition of the propositional attitudes. The same idea can be applied to other webs of theoretical terms. A very simple case is the definition of a wife as someone with a husband, and a husband as someone with a wife. We remove the air of circularity when we note that we could spell matters out as follows: *x* is a wife if there are two people, one male and one female, they are married to each other, and *x* is the female one. Consider, for a more complex example, the artworld and its denizens. Artists are producers of art works. Audiences are viewers or consumers of art works. Critics are critical assessors of art works. Galleries are places for the exhibition of art works. And art works are objects produced by artists for consumption by audiences, assessment by critics and display in galleries. Taken together, these sentences - or some more elaborate version thereof - can be taken to provide a simultaneous definition of the key terms: artist, audience, critic, gallery, artwork. And there is no (vicious) circularity involved because the other terms which feature in the various sentences - ‘production’, ‘consumption’, ‘display’, ‘object’, ‘view’, and so on - are (assumed to be) independently understood. These terms in effect specify the key interconnections, and the definition of artist, work of art, and so on that is delivered amounts to saying that an artist is anyone who is appropriately interconnected.

The sentences which are collected together are either *prima facie* analytic truths - that is, conditionals and biconditionals which encode the inferential practices constitutive of possession of the concepts under analysis - or else claims involving the concepts to be analysed which are regarded as *prima facie* common knowledge by those, or most of those, who possess the concepts. Under the former account, there is no guarantee that the sentences will be immediately available to those who possess the concepts; however, it might be hoped that reasonable and reflective people can be brought to assent to them when the sentences are drawn to their attention. Under the latter account, there is no requirement that the sentences encode inferential practices constitutive of possession of the

concepts under analysis: for all kinds of synthetic and a posteriori claims may be selected. However, the following constraint is to be observed: it should be commonly held to be a condition on attribution of possession of the concepts which are up for analysis to a subject that they do not reject, or fail to accept, too many of the chosen sentences.

On either account, one might doubt that there are sentences of the kind required by the analysis. So, for example, it might be said that it is notoriously difficult to provide exceptionless generalizations about the connections between beliefs, desires, intentions, actions, and so on. However, it is important to note that there is nothing in the account which requires that the platitudes in question must be couched as exceptionless generalisations. Indeed, a plausible thought is that most of the platitudes will instead make claims about what is normally the case - that is about what happens when all other things are equal, or when conditions are normal. So, for example, on either account, there are sentences like these: a system of beliefs and desires tends to cause behaviour that serves the subject’s desires according to that subject’s beliefs; beliefs typically change under the impact of sensory evidence; desires aim to have the world fit them; beliefs aim to fit the world, and so on.

The final point to note is that our definition tells us that the propositional attitudes are whatever it is that satisfies the chosen set of sentences and so stand in the specified relations. In the simplest case, there will be a unique natural collection of candidates for the propositional attitudes. In that case, the sentences provide an explicit definition of the propositional attitudes. But things may not be so simple: perhaps there is nothing which satisfies the sentences exactly; and perhaps the only thing which satisfies the sentences is extremely unnatural, that is, gerrymandered. In these cases, we shall look for the best near-satisfier, where the criteria which guide our search are (1) considerations of naturalness; and (2) satisfaction of as many as possible of the more central platitudes. Put another way: application of a procedure which aims at achieving reflective equilibrium may lead to the rejection of some of the sentences, and perhaps to the elevation of further sentences to membership of the favoured class. Moreover, the procedure which aims at achieving reflective equilibrium is guided by judgments about (1) the naturalness of the resulting concept; and (2) the centrality or revisability of the sentences which are incorporated or rejected.

Of course, there is nothing in the account of this procedure which guarantees that there will be a point of reflective equilibrium: and, in the case in which there is no point of reflective equilibrium, we will need to give an error theory of the propositional attitudes - that is we will hold either that there were no coherent concepts characterized by our pre-reflective usage, or else that there simply is nothing to which our concepts apply.

6 Scepticism about propositional attitudes

There are various sceptical doubts which philosophers have had about propositional attitudes. Only some of these doubts will be mentioned here.

Some philosophers - W.V.O. Quine, Paul Churchland, Stephen Stich, for example - deny that there are any propositional attitudes - they deny that there are any beliefs, desires, intentions and the like. Sometimes, the source for this denial is philosophy of language (dislike of intensional contexts, and so on); other times, the source is metaphysics (failure to find a physical structure with which the states in question can be identified, for example). Sometimes, the view is that propositional attitudes are convenient fictions - useful instruments for making predictions of behaviour, but not suited to the business of serious science. On this view, talk of propositional attitudes has a second grade, merely instrumental, status, but there is no reason why we should not continue with it for purposes of prediction and explanation - a common comparison is with talk about the average family. Other philosophers argue that talk of propositional attitudes is intended as first grade scientific theorizing, but that it just happens to be seriously astray. On this view, talk of propositional attitudes is like talk of phlogiston: talk which sought to capture an important feature of reality and to be part of serious science, but failed (see Eliminativism).

Among philosophers who accept that there are propositional attitudes - that is, among those philosophers who accept that some propositional attitude ascriptions are strictly and literally true - there are philosophers who are sceptical of the relational analysis of those attitudes. Thus, some philosophers suppose that propositional attitudes should be given an adverbial analysis according to which, for example, one’s belief that p is a matter of one’s believing p-ly (see Adverbial theory of mental states). They deny that the attitudes are relations to propositions. Sometimes, this denial is fuelled by worries about the candidate entities for those contents, the sets of worlds,

structured set-theoretic entities, and the like we discussed earlier. Theorists who deny the relational view of the attitudes typically insist that a sentence like ‘I believe that snow is white’ is best written, from a logical point of view, as ‘I snow-is-white believe’, somewhat as ‘I have a limp’ is best written ‘I limp’.

Yet other philosophers - Stephen Schiffer, for example - despair of the project of giving any philosophical account (theory, analysis) of propositional attitudes, while nonetheless supposing that our practice of making propositional attitude ascriptions is perfectly in order as it stands. The essence of their position is a denial of the need to give an account in anything like the traditional sense of the propositional attitudes.

Theorizing about propositional attitudes is a very difficult task. This brief summary only indicates a few of the controversial questions which such theorizing is bound to confront.

Propositions, sentences and statements

A sentence is a string of words formed according to the syntactic rules of a language. But a sentence has semantic as well as syntactic properties: the words and the whole sentence have meaning. Philosophers have tended to focus on the semantic properties of indicative sentences, in particular on their being true or false. They have called the meanings of such sentences 'propositions', and have tied the notion of proposition to the truth-conditions of the associated sentence.

The term 'proposition' is sometimes assimilated to the sentence itself; sometimes to the linguistic meaning of a sentence; sometimes to 'what is said'; sometimes to the contents of beliefs or other 'propositional' attitudes. But however propositions are defined, they must have two features: the capacity to be true or false; and compositional structure (being composed of elements which determine their semantic properties).

One reason for distinguishing a sentence from 'what the sentence says' is that a sentence may be meaningless, and hence say nothing, yet still be a sentence. But perhaps the main reason is that two people, *A* and *B*, may utter the same sentence, for example, 'I am hot', and say the same thing in one sense but not in another. The sense in which they say the same thing is that they use the same words with the same linguistic 'meaning'. The sense in which they say something different is that they put the same words to different 'uses': *A* uses 'I' to refer to *A*, while *B* uses it to refer to *B*. Hence what *A* says may be true although what *B* says is false. If what is said can be true in one case and false in another, *A* and *B* have not made the same 'statement'. On the other hand, if *B* utters instead 'You are hot' when *A* utters 'I am hot', they put different sentences to the same use and make the same statement. On this view (see Strawson 1952), we must distinguish the 'sentence', the 'use' of the sentence, and the 'statement' made by using a sentence in a context of utterance. According to Strawson, it is not sentences but statements that are true or false.

Logicians usually abstract from the context of utterance of sentences in actual communication and talk of the propositions expressed as abstract entities. The main modern proponent of this conception is Frege. For Frege (1918), a proposition is a 'thought', which is both the cognitive meaning expressed by a sentence and the content of a propositional attitude such as belief or desire; thoughts are the 'senses' of sentences. Thoughts are distinguished according to the following principle: if it is possible rationally to believe that *p* and not to believe that *q* then the thought that *p* and the thought that *q* are distinct (see Frege, G. §§3-4; Sense and reference §2).

Under a different, but related, conception, proposed by Carnap (1947), the proposition expressed by a sentence *S* is the set of possible worlds in which *S* is true (see Semantics, possible worlds §9-10). This view violates the compositional structure requirement, since such propositions are not grasped by grasping their components (see Compositionality). It also seems unable to differentiate between some distinct propositions. For example, there would only be one necessarily false proposition, since there is only one empty set of worlds, but intuitively there are many different necessarily false propositions.

An alternative view of propositions as entities is the (neo-)Russellian view that they are collections of actual entities making up 'facts' or 'states of affairs' (see Facts §1). Thus the proposition expressed by 'Socrates is mortal' is the ordered pair $\langle \mathrm{Socrates,\ being\ mortal} \rangle x$, composed of the individual Socrates and the property of being mortal. Three questions for this view are: (1) Are the contents of false sentences negative facts, and are there such facts? (2) What is the criterion of identity for facts? (3) How can propositions as facts be the contents of propositional attitudes? The last of these can be seen as a version of the problem which led Frege to postulate senses: for the fact that $a = b$ must be the same fact as $a = a$, although someone who believes that $a = a$ does not thereby believe that $a = b$, and hence the propositions are not the same (see Sense and reference §1). Fregeans conclude that this shows that we cannot dispense with the notion of sense. If Russellians deny this, they must complicate their account of facts or their account of propositional attitudes (see Propositional attitude statements).

Whether one defines the intuitive notion of 'what is said' as a context-independent entity or by recourse to the notion of a statement or proposition expressed by an utterance in a particular context, one must say what it means for two sentences to express 'the same proposition' or make 'the same statement'. Both phrases rely on the notions of meaning and synonymy, criticized by Quine (1968; see Quine, W.V. §8). But if we dispense altogether with

propositions, statements or any other notion of the content of what is said, and choose instead to take sentences as truth bearers, we face two problems. The first is that sentences are unlikely candidates for the role of contents of propositional attitudes: if ‘I believe I am stupid’ introduces a relation between me and the English sentence ‘I am stupid’, it should be translated into German (say) as ‘Ich glaube "I am stupid"’, although the correct translation is ‘Ich glaube daß ich dumm bin’, which says nothing about any English sentence (Church 1950). The second problem is that, in spite of our ontological scruples about admitting propositions as entities, we still need such a notion to express the content of what is said or believed, and to account for the intentionality of thought in general. In that respect, however vague or ill-defined the notion of a proposition, it cannot be dispensed with.

Protagoras (*c*.490-*c*.420 BC)

*Protagoras was the first and most eminent of the Greek Sophists. Active in Athens, he pioneered the role of professional educator, training ambitious young men for a public career and popularizing the new rationalist worldview that was introduced from Ionian natural philosophy. But unlike his contemporary Anaxagoras, Protagoras was sceptical of the dogmatic claims of the new science. His famous formula - 'Man is the measure of all things, of things that are, that they are, and of things that are not, that they are not' (fr. 1) - makes him the father of relativism and even, on some interpretations, of subjectivism. He was also considered the first theological agnostic: 'Concerning the gods, I am unable to know either that they exist or that they do not exist or what form they have' (fr.4). He was sometimes associated with the claim 'to make the weaker argument (*logos*) the stronger'.*

1 Career

Protagoras came from Abdera, the city of the atomist Democritus. As a professional educator, he visited Athens several times and was closely connected with the intellectual circle around the leading statesman Pericles. He is reported to have drawn up the laws for Thurii, a pan-Hellenic colony in southern Italy, founded on the site of Sybaris in 444 BC under Periclean leadership. His extraordinary prestige, as the wisest person and greatest teacher of his time, is brilliantly portrayed in the introductory scenes of Plato's dialogue *Protagoras* (see Plato §9). Protagoras there declares that he is the first Greek openly to offer moral and political training on a professional basis.

Protagoras' agnosticism regarding the existence of the gods must have shocked many of his contemporaries. A widespread ancient tradition reports that he escaped from Athens after being condemned for impiety, and that he was subsequently drowned at sea. One version of the story claims that his books were publicly burned at Athens. Some scholars have doubted this report, on the grounds that in Plato's *Meno* (91e) Socrates says that Protagoras remained in good repute until the end of his life. On the whole, however, the ancient tradition is likely to be correct. If so, Protagoras was (like Anaxagoras) one of the first victims of the popular reaction against the rationalist Enlightenment, whose most famous victim was Socrates (§1).

2 Teaching

In Plato's *Protagoras*, Protagoras describes the content of his teaching as 'good judgment in administering the affairs of one's household and those of the city, so that one may be most capable of acting and speaking on public matters' (319a). He there declares that if any pupil is not satisfied with the requested fee (which was certainly high), he need only go to a temple to swear how much he thinks the training was worth, and pay no more. The primary appeal of his teaching was to ambitious young men from wealthy families, who hoped to gain an advantage for their political career from studying with him. In historical perspective, the Sophistic movement initiated by Protagoras can be seen as the beginning of higher education in Western culture. The Sophists were the first professors without a permanent school (see Sophists).

Unlike some later Sophists who included the new natural philosophy in their curriculum, Protagoras seems to have focused his own training on practical concerns, and above all on eloquence and argument. He is credited with being the first to show that there can be an argument for and against every thesis (fr. 6a). Thus he is reported to have trained his students, like a modern debater, to argue both sides of every disputed question, and also to be able to praise and blame the same person (A20-1). We have in the *Dissoi logoi (Twofold Arguments)* an ancient collection of sample reasoning on opposite sides of issues concerning good and bad, just and unjust, whether virtue can be taught, and the like (see Dissoi Logoi). The extant text of *Dissoi logoi* is estimated to postdate Protagoras, but manuals of this type probably represent a tradition of *antilogia* or contradictory argumentation going back to Protagoras. It was presumably because Protagoras was so celebrated as a master of argument and refutation that Plato has selected him as Socrates' opponent and victim in the duel of wits in the dialogue *Protagoras*.

Protagoras' teaching is associated with the claim 'to make the weaker argument the stronger'. This is easily given a hostile interpretation: to make a bad case seem good, and thus to deceive a gullible audience. Enemies of the Sophists like Aristophanes certainly took this view of the kind of training that Protagoras inaugurated, and they regarded the moral influence of the Sophists as nefarious. Protagoras himself, however, seems to have been a

staunch defender of traditional morality. This is indicated not only by Plato's portrayal but also by his political role as legislator for Thurii. The contrast between *nomos* and *physis*, between conventional morality and the nature of things, was later used to undermine the authority of the moral tradition (see Antiphon; Callicles; Physis and nomos). If this contrast was used by Protagoras (as some scholars have supposed), it can only have functioned in favour of *nomos* and the customary moral tradition. For, as will be seen in §3, Protagoras denies the claims to absolute or objective knowledge associated with the notion of *physis*. For a relativist like Protagoras there is no knowledge of the nature of things except from a particular human perspective.

Protagoras was also a pioneer in the study of language and grammar. Two important grammatical observations are attributed to him: (1) the distinction of gender into masculine, feminine and neuter (A27), and (2) the distinction of discourse into prayer (or optative), question (interrogative), answer (indicative), and command (imperative) (A1, paragraph 53, where a more complex division is also ascribed to Protagoras). These grammatical distinctions were apparently developed in the context of critical comments on Homeric poetry in the name of *orthoepeia* or correctness of diction. Thus Protagoras is reported to have disapproved of the opening verses of the *Iliad* for using an imperative form ('Sing, muse, of the wrath of Achilles') rather than the optative, which would be more appropriate for a prayer (A29). And he seems also to have complained that Homer's word 'wrath' (*menis*) should be masculine rather than feminine (A28). Plato twice alludes to Protagoras as an expert on the correctness of names (*Cratylus* 391c) or the correctness of diction (*Phaedrus* 267c) and he presents Protagoras as claiming that skill in criticizing the poets constitutes a major part of education (*Protagoras* 338e). The complex concern with language that is characteristic of Sophist practice thus clearly begins with Protagoras, but our evidence is too meagre for an accurate appreciation of his personal contribution.

3 Philosophical views

Protagoras is famous for two quotations. The best known is from a book entitled *Truth*: 'Man is the measure of all things, of things that are, that they are, and of things that are not, that they are not' (fr.1). The other may be from a different work: 'Concerning the gods, I am unable to know either that they exist or that they do not exist or what form they have. For there are many obstacles to knowledge: the obscurity of the matter and the brevity of human life' (fr.4). There is at least a notional connection between these two doctrines, since the claims to dogmatic knowledge on the part of early poets and philosophers often invoke divine inspiration. Thus Parmenides, the most influential philosopher of the fifth century, presents his view as the revelation of a goddess. In rejecting any knowledge of the gods, Protagoras also rejects any claim to an absolute or god's-eye knowledge of the truth.

Protagoras' 'man-the-measure' formula was interpreted in two different ways: (1) the subjectivist interpretation takes the thesis to claim that whatever anyone believes is true; and (2) the relativist interpretation claims only that whatever anyone believes is true for the person who believes it. The subjectivist doctrine (1) is rather easy to refute. For if all beliefs are true, then the belief that the man-the-measure doctrine is false must also be true. So if anyone doubts the truth of the man-the-measure thesis, the thesis itself must be false. This is the argument known as the *peritropē*, the claim that the thesis overturns itself. Plato in the *Theaetetus* interprets Protagoras' doctrine as the relativist thesis (2): that what anyone believes is true *for that person* (see Relativism). Plato presents the *peritropē* argument as a refutation of this version also.

We do not know whether or not Protagoras applied his theory of truth to moral and political issues. Plato suggests that for Protagoras: 'whatever the city establishes as just, is just for that city as long as it judges so' (*Theaetetus* 177d). This form of cultural relativism, which combines the recognition of different moral codes with respect for established tradition, is likely to be historically correct for Protagoras, since we find a similar regard for *nomos* or custom, in the face of cultural diversity, defended by Protagoras' contemporary, the historian Herodotus. It would also be a convenient doctrine for an itinerant philosopher, who can thus endorse the established order in each society when travelling from city to city.

Other positions attributed to Protagoras may be connected with his relativist theory of truth. Thus it may have been a general reaction against dogmatic claims that led him to deny that the circle touches a straight line only at a single point, as is assumed in plane geometry (fr. 7). The paradoxical view that 'it is not possible to contradict someone', which was later defended by Antisthenes (§4), was originally ascribed to Protagoras. If all opinions are true, then two speakers who seem to disagree cannot really be contradicting one another: they must be talking about different things.

Proudhon, Pierre-Joseph (1809-65)

Pierre-Joseph Proudhon was a French social theorist, political activist and journalist. Claiming to be the first person to adopt the label 'anarchist', he developed a vision of a cooperative society conducting its affairs by just exchanges and without political authority. In his lifetime he exercised considerable influence over both militants and theorists of the European left, and he is remembered today as one of the greatest exponents of libertarian socialism. His last writings, though still strongly libertarian, advocated a federal state with minimal functions.

Proudhon was born in Besançon, in the French Jura, to a poor artisan family. He worked first as a printer, and was largely self-educated. At the age of thirty he won a fellowship from the local Academy and went to Paris, where he spent most of the rest of his life. During the 1840s his writings included *Qu'est-ce que la propriété? (What is Property?)* (1840), and *Système des contradictions économiques ou Philosophie de la Misère (System of Economic Contradictions, or the Philosophy of Poverty)* (1846), which laid the groundwork for his social and economic theory: the latter drew an acerbic reply (*The Poverty of Philosophy*) from Marx, who regarded Proudhon's views as those of a petit-bourgeois. By the time of the 1848 revolution he was prominent enough to win election to the Constituent Assembly, where, however, he was too isolated a figure to be effectual. After the advent of the Second Empire in 1851, Proudhon suffered periods both of imprisonment in France and exile in Belgium. During this period he wrote some of his most important books, notably his three-volume *De la justice dans la Révolution et dans l'Église (On Justice in the Revolution and in the Church)* (1858). Five years after Proudhon's death, many leaders of the Paris Commune, the most important socialist insurrection ever to take place in Western Europe, regarded themselves as his disciples. Russian anarchists, such as Tolstoi and Kropotkin, also acknowledged his influence.

Proudhon wrote in a muscular and impetuous style, often producing startling aphorisms, which on first glance may seem to be paradoxes. The two for which he is best known are 'property is theft' and 'God is evil'. Neither of these, however, can be taken at face value. With regard to the first aphorism, Proudhon believed that possession of a share in productive resources was immensely important: it was essential to the development of the (male) individual's inventive and productive powers. What he rejected as 'theft' was the existence of a property right which confirmed some people in their possession of resources, when others possessed none. Proudhon favoured a society in which possession of productive resources would be widely shared (in contrast to the collective ownership favoured by socialists such as Marx (see Marx, K. §12)). Producers would exchange their goods, not at a market price determined by the interaction between supply and demand, but at a price fixed by the average labour time required by the goods' production. Efficient producers would thus be rewarded.

The second famous aphorism, 'God is evil', also requires a context. Proudhon equates 'God' with ideas of fatality which exclude or downplay the idea of human agency. When he says, in *System of Economic Contradictions*, that 'the first duty of the free and intelligent man is to hunt the idea of God from his mind', he means that, to be free, people must abandon the idea that human circumstances are something other than a human construct. Part of unfreedom is the belief that the evolution of human society is the work of fate or providence and thus beyond the control of humans: this belief will vanish when there are no longer massive concentrations of economic and political power which remove decisions from the hands of ordinary people. Another part of unfreedom is the belief that one must obey authorities endowed with some special status which places them beyond the control of their subjects, an irrational belief which would not survive without religious support.

Independence - material and intellectual - was thus an important value for Proudhon. But he also stressed the interdependence arising from the complementarities in social life. The complementarity of different skills creates an incentive to reach agreement, as well as multiplying the power of human labour. The non-synchronized character of humans' needs makes possible the institution of credit: Proudhon's writings inspired some important practical reforms in the credit system. Interestingly, within the family unit, the principle of interdependence triumphed wholly over that of independence: Proudhon held rigid views about the sexual division of labour, and would have allowed women no role outside the household. Traditionalist aspects of Proudhon's thought have led some right-wing theorists to claim him for their own.

Proudhon's thinking reveals many influences: there are echoes of Fourier, Saint-Simon, Comte, British political

economy, Hegel and Feuerbach. Rousseau (see Rousseau, J.-J. §3), however, has a special importance for him, both positive and negative. What Proudhon shared with Rousseau was the idea that absolute personal independence could be reconciled with the social condition - that one can belong to a social order yet 'obey only oneself' (perhaps in the limited sense of obeying one's own reason). What he hated in Rousseau was the conclusion that this reconciliation could be achieved only in the state: it could best be achieved, Proudhon thought, in civil society, and in the reciprocity among groups of producers, characterized by mutual respect and complementarity of interest. Proudhon was a critic of political democracy, which he thought Rousseau had inspired: although he believed in the capacity of small groups to manage concrete affairs which they could understand, he had no faith in the political discernment of the masses. When he came eventually to accept the need for government, he did so only on the condition that the primary units of government would be small communities constrained by immediate responsibility for their decisions: the radically decentralizing spirit of his earlier work is not abandoned.

Provability logic

Central to Gödel's second incompleteness theorem is his discovery that, in a sense, a formal system can talk about itself. Provability logic is a branch of modal logic specifically directed at exploring this phenomenon. Consider a sufficiently rich formal theory T. By Gödel's methods we can construct a predicate in the language of T representing the predicate 'is formally provable in T'. It turns out that T is able to prove statements of the form

(1) If A is provable in T, then it is provable in T that A is provable in T.

In modal logic, predicates such as 'it is unavoidable that' or 'I know that' are considered as modal operators, that is, as non-truth-functional propositional connectives. In provability logic, 'is provable in T' is similarly treated. We write $\Box A$ *for 'A is provable in T'. This enables us to rephrase (1) as follows:*

(1′) $\Box A \rightarrow \Box\Box A$.

This is a well-known modal principle amenable to study by the methods of modal logic.

Provability logic produces manageable systems of modal logic precisely describing all modal principles for $\Box A$ *that T itself can prove. The language of the modal system will be different from the language of the system T under study. Thus the provability logic of T (that is, the insights T has about its own provability predicate as far as visible in the modal language) is decidable and can be studied by finitistic methods. T, in contrast, is highly undecidable. The advantages of provability logic are: (1) it yields a very perspicuous representation of certain arguments in a formal theory T about provability in T; (2) it gives us a great deal of control of the principles for provability in so far as these can be formulated in the modal language at all; (3) it gives us a direct way to compare notions such as knowledge with the notion of formal provability; and (4) it is a fully worked-out syntactic approach to necessity in the sense of Quine.*

1 The prehistory of the subject

The history of provability logic proper starts with Kurt Gödel (1933), who, at the end of a discussion of the interpretation of intuitionistic propositional logic, briefly (in six lines!) discusses formal provability as a modal operator.

The next step was taken by Leon Henkin who, in 1952, asked a seemingly frivolous question:

> If Σ is any standard formal system adequate for recursive number theory, a formula (having a certain integer *q* as its Gödel number) can be constructed which expresses the proposition that the formula with Gödel number *q* is provable in Σ. Is this formula provable or independent in Σ?
>
> (Henkin 1952: 180)

In short, is a sentence that 'says' 'I am provable in Σ' provable in Σ? Note that $\underline{0} = \underline{0}$ is a fixed point of $\mathrm{Prov}_T(x)$: $\underline{0} = \underline{0}$ is provable in *T* and so is $\mathrm{Prov}_T(\underline{\#(\underline{0} = \underline{0})})$; hence, by classical logic, $(\underline{0} = \underline{0} \leftrightarrow \mathrm{Prov}_T(\underline{\#(\underline{0} = \underline{0})}))$ is provable in *T*. (See §2 below for an explanation of the notation.) $\underline{0} = \underline{0}$ is, however, not a *literal* Henkin sentence: it is not built explicitly to say of itself 'I am provable' in the way that Gödel's sentence is built to say 'I am not provable'. In 1953, G. Kreisel published a noteworthy paper answering Henkin's question with a resounding 'It depends… '. Kreisel constructed two extensionally correct provability predicates where for the one the literal Henkin sentence ('I am provable in Σ') is provably true, but for the other it is provably false.

It might have ended there. Kreisel's result might have discouraged everyone from thinking further about Henkin's 'frivolous' question. Happily for the subject, a second paper, by M.H. Löb, appeared in 1955. Löb shows that under certain natural assumptions (the ones codified by (L1)-(L3) below) on the provability predicate, the answer to Henkin's question is that the literal Henkin sentence is true. In fact, under these conditions every solution to the 'Henkin equation' is provably true. With the formulation of the Löb conditions the modal study of provability could begin. For a good part of the subsequent story the reader is referred to Boolos and Sambin (1991).

2 What is provability logic?

Provability logic is best described as the sustained investigation of formal provability and related notions as modal operators. Consider the language L of modal propositional logic (see Modal logic). Let A be a language of predicate logic and let *T* be a theory in A. *T* should satisfy a number of conditions, which we will specify later. For the moment let us simply pretend that A is the language of arithmetic and that *T* is Peano arithmetic (PA). An 'interpretation' $(.)\sigma$ of L in A with respect to *T* is given by a mapping σ of the propositional variables to sentences of A. This mapping is extended to a full interpretation via the following clauses:

$$\begin{aligned}
(p)\sigma &= \sigma(p),\\
(\bot)\sigma &= \bot,\ (\top)\sigma = \top,\\
(A \wedge B)\sigma &= (A)\sigma \wedge (B)\sigma,\\
(A \vee B)\sigma &= (A)\sigma \vee (B)\sigma,\\
(A \rightarrow B)\sigma &= (A)\sigma \rightarrow (B)\sigma,\\
(\Box A)\sigma &= \mathrm{Prov}_T(\underline{\#((A)\sigma)}).
\end{aligned}$$

Only the last clause deserves comment. Prov_T is the arithmetized provability predicate for *T*. $(A)\sigma$ is a sentence of A. $\#((A)\sigma)$ is the Gödel number of $(A)\sigma$. Finally, $\underline{\#((A)\sigma)}$ is the numeral of $\#((A)\sigma)$. Thus $\underline{\#((A)\sigma)}$ is a closed term of A denoting $\#((A)\sigma)$ under the standard interpretation. For example, $(\neg\Box\bot)\sigma$ translates to $\neg\mathrm{Prov}_T(\underline{\#(\bot)})$, the sentence expressing the consistency of *T*. $\underline{\#((A)\sigma)}$ is, in a sense, the obvious way available to *T* to talk about $(A)\sigma$.

The meaning of ' $(.)\sigma$' depends on the given *T*. Strictly speaking we should write ' $(.)(\sigma, T)$', or something similar, to make the dependence on *T* visible. However, to avoid too heavy a notational burden, we 'hide' *T*.

In the definition of $(A)\sigma$ a subformula occurrence of *B* in *A* can 'go to' two different things. If the occurrence is not in the scope of a ' $\Box$', then *B* translates to a formula of A. If the occurrence is in the scope of a ' $\Box$', then the translation of *B* contributes to the value of a term in $(A)\sigma$. This difference in treatment leads to the existence of modalized fixed points. Let us remind ourselves of the Gödel fixed point lemma (see Gödel's theorems). For any formula $C(x)$ of A with at most *x* free, there is a sentence *D* of A, such that $T \vdash D \leftrightarrow C(\underline{\#(D)})$. Observe that *D* 'occurs' in two different ways in the fixed point statement - as a formula and as a term. The fixed point lemma has the 'fixed point theorem' (1) below as a correlate in the modal language.

To formulate (1) we first give a definition. We say that *p* occurs 'only modalized' in *A* if all occurrences of *p* in *A* are in the scope of a box. For example, *p* occurs only modalized in $\Box(p \rightarrow \Box\Box p)$; *p* does not occur only modalized in $p \wedge \Box p$. Note that if *p* does not occur in *A* at all, then it occurs only modalized in *A*.

(1) Suppose that *p* occurs only modalized in *A*. Consider any σ from the propositional atoms to the sentences of A. We can find a *D* in A such that if τ is the function such that $\tau(q) = \sigma(q)$ for $q \neq p$ and $\tau(p) = D$, then we have $T \vdash (p \leftrightarrow A)\tau$.

For example, we can find a τ such that $T \vdash (p \leftrightarrow \neg\Box p)\tau$. Note that this is just a reformulation of the most celebrated application of the Gödel fixed point lemma: the proof of the existence of a Gödel sentence *G* such that

$T \vdash G \leftrightarrow \neg\mathrm{Prov}_T(\underline{\#(G)})$.

Note that if we were to drop the 'guardedness condition', that *p* must be only modalized, then we would immediately get the liar paradox by taking $A = \neg p$. We will see below that (1) has an unexpected improvement in (4).

Let Γ be a finite set of L-formulas. We write $(\Gamma)\sigma$ for $\{(A)\sigma | A \in \Gamma\}$. We define $\Gamma \models_T A$ (pronounced '*A* is a *T*-consequence of Γ') to mean that for all σ,

$T + (\Gamma)\sigma \vdash (A)\sigma$.

'$\models_T$' is a relation of arithmetical validity (with respect to *T*) for the modal language. Interpretations take the place of semantics in this definition. The dependence on *T* in the definition is two-fold: first, we are considering

principles derivable in *T*; second, the interpretation of '$\Box$' under the $(.)\sigma$ is the arithmetization of the predicate 'is provable in *T*'.

We have, for example, $\Box p \models_T \Box\Box p$. Translating this back we find that it means that, for all sentences *A* of the language of *T*,

$$T + \mathrm{Prov}_T(\underline{\#(A)}) \vdash \mathrm{Prov}_T(\underline{\#(\mathrm{Prov}_T(\underline{\#(A)}))}).$$

You could say that $\Box p \models_T \Box\Box p$ expresses the validity of a schematic step with respect to *T*. The unusual thing is that the schema is formulated in a different kind of language: the language of modal propositional logic, which contains a logical operator not occurring in the language of *T*.

The relation '$\models_T$' can be axiomatized by a theory called Löb's logic (L or PrL for provability logic, or GL for Gödel-Löb logic) with the following rules of proof:

(L1) $\vdash A \Rightarrow \vdash \Box A$
(L2) $\vdash \Box(A \rightarrow B) \rightarrow (\Box A \rightarrow \Box B)$
(L3) $\vdash \Box A \rightarrow \Box\Box A$
(L4) $\vdash \Box(\Box A \rightarrow A) \rightarrow \Box A$.

(L4) is also known as Löb's principle. In view of the fact that in classical logic an implication follows from its consequent, Löb's principle tells us that an instance of the reflection principle $\vdash \Box A \rightarrow A$ is *only* provable if its consequent is already provable. In other words, *T* 'knows' that it can prove only trivial instances of reflection.

The soundness of L was, in effect, proved by M.H. Löb (1955). Completeness was proved by R. Solovay (1976). 'Solovay's completeness theorem' is as follows:

(2) Under appropriate conditions on the theory *T* (see below), $\mathrm{L} + \Gamma \vdash A \Leftrightarrow \Gamma \models_T A$.

L has a Kripke-type completeness theorem with respect to transitive models with an upwardly well-founded accessibility relation. (The accessibility relation is upwardly well-founded if there are no infinite ascending chains.) Since the logic has the finite model property, we have Kripke completeness also with respect to finite, transitive, irreflexive models. The logic is not compact for the Kripke semantics: one can produce an infinite set *X* of modal formulas that cannot be valid on any transitive, upwardly well-founded model. On the other hand, for every finite subset X_0 of *X* one can find such a model on which X_0 is valid.

There are two major results about what L can prove. The first (due to Bernardi, de Jongh and Sambin) is the fact that fixed points of modalized formulas are unique. The theorem says that if *p* and *q* are truly and provably fixed points of *A*, then they are truly and provably equivalent. We write $A(B/p)$ for the result of substituting *B* for *p* in *A*. Define $\Box^+ A := A \wedge \Box A$.

(3) Suppose that *p* occurs only modalized in *A* and that *q* does not occur in *A*. Then

$$\Box^+(p \leftrightarrow A), \Box^+(q \leftrightarrow A(q/p)) \vdash \Box^+(p \leftrightarrow q).$$

The second major result (due to de Jongh and Sambin) is the existence of explicit fixed points. The theorem says that the language L is rich enough to contain explicit definitions of the fixed points of formulas (with respect to propositional variables which occur only modalized in them).

(4) Suppose that *p* occurs only modalized in *A*. Then there is a *B* in L containing only variables occurring in *A*, but not containing *p*, such that $\vdash B \leftrightarrow A(B/p)$.

The proof of (4) yields an algorithm for computing *B* from *A* and *p*.

To illustrate (1), (3) and (4), consider $\neg\Box p$. (1) tells us that in the arithmetical interpretation this formula has a fixed point: precisely the celebrated Gödel sentence *G*. (3) tells us that, modulo provable equivalence in *T*, this sentence is unique. (4) tells us that we can find an explicit equivalent of *G* in the modal language. If we apply the algorithm associated to (4), we find that the explicit fixed point is $\neg\Box\bot$, the sentence expressing the consistency of *T*. Thus (4) links the unprovable sentence of Gödel's first incompleteness theorem to the unprovable sentence of

Gödel's second incompleteness theorem (see Gödel's theorems).

The difference between (1) and (4) is as follows. (1) tells us that for all interpretations of the propositional variables (except *p*) of *A* (with *p* modalized), we can assign a sentence to *p* yielding the fixed point property. *Prima facie* this sentence need not be expressible in the modal language. (4) tells us that the modal language is rich enough to define the fixed point explicitly.

We close this section with some remarks about the precise choice of the theory *T* and A, the language of *T*. To make the results above work, *T* must be rich enough to do arithmetization in. This means that a sufficiently rich theory of arithmetic must be interpretable in *T*. The most natural choice for this theory is Buss' S^1_2, a theory far weaker than such well-known theories as primitive recursive arithmetic, $\mathrm{I}\Sigma^0_1$ or PA. The theory S^1_2 is not contained in $\mathrm{I}\Delta_0$. S^1_2 has induction restricted to the Σ^b_1-formulas, a class connected to the logical study of feasible algorithms (see Complexity, computational). $\mathrm{I}\Delta_0$ has induction restricted to the Δ_0-formulas. In S^1_2 some functions are provably total which are not provably total in $\mathrm{I}\Delta_0$. It turns out that the presence of S^1_2 is sufficient to verify the validity of L. However, to prove Solovay's completeness theorem (2) we seem to need more. Inspection of Solovay's proof shows that the theory we (*prima facie*) need is $\mathrm{I}\Delta_0 + \mathrm{Exp}$. Here Exp is an axiom expressing that the exponentiation function is total. It is consistent with everything we know that S^1_2 has a provability logic that is stronger than L! We can now give the first condition that the theory *T* should satisfy to be sound and complete for Löb's logic.

Condition 1: $\mathrm{I}\Delta_0 + \mathrm{Exp}$ is interpretable in *T*.

We do not demand that $\mathrm{I}\Delta_0 + \mathrm{Exp}$ be literally a sub-theory of *T*, since we want the results of provability logic to be applicable to such theories as ZF (see Set theory) in which arithmetic is present only via a translation of the arithmetical language into the language of set theory.

A second condition on the theory is that it be sufficiently sound. For example, by the second incompleteness theorem $U := \mathrm{PA} + \mathrm{Prov}_{\mathrm{PA}}(\underline{\#(\bot)})$ is consistent. As is easily seen, $U \vdash \mathrm{Prov}_U(\underline{\#(\bot)})$. So $\models_U \Box\bot$ and, hence, Solovay's completeness theorem cannot hold for *U*. We exclude such theories as *U* by demanding that *T* is Σ_1-sound, that is, the Σ_1-sentences *T* proves are all true. (A somewhat sharper condition is possible, but space does not permit its introduction here.)

Condition 2: *T* is Σ_1-sound.

3 What does provability logic achieve?

We end with some comments on the usefulness of provability logic. First the mathematical side. Clearly the modal presentation of arithmetical arguments makes them very perspicuous. So provability logic achieves Kreisel's excellent aim of 'saying simple things simply'. Also, by Solovay's theorem, provability logic completely describes the arithmetically valid modal provability principles. Moreover, it enables us to study these principles using the tools of modal logic (for example, Kripke semantics). Thus, by switching to the modal language, we gain control.

Now for philosophical relevance. Provability logic offers a fully worked-out syntactic treatment of modality (in the sense of Quine 1953). Since its principles are quite different from what one would ordinarily expect of notions of knowledge, necessity and so on, one way of viewing what is achieved is to conclude that syntactic treatments of such notions are not possible (for a brief discussion, see Thomason 1980). Moreover, comparing intuitively plausible modal principles for notions such as knowledge, human provability and the like with the principles satisfied by formal provability gives some sense of how these notions differ from formal provability. The reflection principle $\vdash \Box A \rightarrow A$ is built into or internal to the ordinary notions of knowledge and (human) provability. In contrast, formal provability satisfies Löb's principle ($\vdash \Box(\Box A \rightarrow A) \rightarrow \Box A$). We can 'see' that the difference between human and formal provability is not simply one of *strength* (but, I would suggest, one of *kind*). (The popularity of the view that the difference is one of strength can be seen, for example, in the discussion concerning minds and machines, where it is sometimes claimed on the ground of Gödel's incompleteness theorems that humans can beat machines in a theorem-producing game.)

Löb, M.H. (1955) 'Solution of a Problem of Leon Henkin', *Journal of Symbolic Logic* 20: 115-18.(As the title of this paper suggests, Löb answered Henkin's problem, and also proved the soundness of Löb's logic.)

Quine, W.V. (1953) 'Three Grades of Modal Involvement', in *Proceedings of the 11th International Congress of Philosophy* 14, Amsterdam: North Holland, 65-81.(Quine shows that provability logic offers a fully worked-out syntactic treatment of modality.)

Smorynski, C. (1985) *Self-Reference and Modal Logic*, New York: Springer.(A well-written and elegant textbook; includes good discussions of multi-modal provability logic and of non-extensional self-reference.)

Solovay, R.M. (1976) 'Provability Interpretations of Modal Logic', *Israel Journal of Mathematics* 25: 287-304.(A proof of the completeness of Löb's logic.)

Thomason, R.H. (1980) 'A Note on Syntactical Treatments of Modality', *Synthèse* 44: 391-5. (Presents the view that syntactic treatments of knowledge, necessity and so on are not possible.)

Providence

Divine providence is God's care, provision, foresight and direction of the universe in such a way that the universe as a whole and individual creatures within it fulfil God's purposes. Belief in providence was affirmed by some Greek philosophers (especially the Stoics), and is a fundamental tenet of Judaism, Christianity and Islam. In modern times, questions have arisen about the possibility of divine intervention in worldly affairs; this creates a difficulty for belief in providence, because it makes it hard to see how God can shape events so as to carry out his providential purposes.

Theories of providence differ with regard to the extent to which God has direct and specific control over earthly events, as opposed to guiding the course of affairs in a general way towards his overall goals. The strongest affirmation of divine control comes from Calvinism, which accepts a compatibilist view of free will (that is, that free will is compatible with determinism) and affirms God's absolute control over everything that happens. Other views affirm libertarian free will for creatures; some place limitations on God's knowledge of the future, and process theology places stringent limits on God's power to affect worldly events. These limitations tend to give creatures a limited degree of independence over against God, and lessen God's direct and specific control over events.

1 A brief history of providence

Belief in a personal or quasi-personal deity has often been virtually synonymous with belief in some kind of divine providential governance of the world. Among the Homeric Greeks, to be sure, fate was an uncanny, impersonal destiny, taking precedence even over the will of the gods. But in Hesiod, the supreme governance of the universe is in the hands of Zeus, who awards both prosperity and punishments in accordance with the law of justice. Plato, in the *Laws*, wrote that 'It is a matter of no small consequence, in some way or other to prove that there are Gods, and that they are good, and regard justice more than men do' (Laws 10). Thus Plato rejected the prevalent mythology because it attributed moral defect to the gods, and the Demiurge of the *Timaeus* 'being without jealousy…desired that all things should come as near as possible to being like himself' (*Timaeus* 29e).

The most serious account of divine providence among the Greek philosophers came from the Stoics. According to them, the ruling power of the universe - God, or the Logos - orders all things for the best in accordance with a universal law of causation. Suffering and calamities are no exception to this. Thus, the path of wisdom is to accept whatever circumstances befall as divinely ordained; one should not complain about the part in the cosmic drama one has been assigned, but rather concern oneself with playing that part in the best way possible. One's inner response to circumstances is to some degree in one's own control; the circumstances themselves are not. It is not surprising that this first attempt to state a rigorous and thoroughgoing account of providence also generated the first major encounter with the problem of evil (see Stoicism §20).

The scriptures of all three major monotheistic religions place great emphasis on divine providence. The Hebrew Bible expresses strongly the belief in God's presence, activity, and direction of all things: 'The Lord is good to all, and his compassion is over all that he has made' (Psalms 145: 9). God's providential rule is seen especially in the history of the Hebrew people: 'For I brought you up from the land of Egypt, and redeemed you from the house of bondage; and I sent before you Moses, Aaron, and Miriam' (Micah 6: 4). But God's hand is not absent from the affairs of other nations: '"Are you not like the Ethiopians to me, O people of Israel?" says the Lord. "Did I not bring up Israel from the land of Egypt, and the Philistines from Caphtor and the Syrians from Kir?"' (Amos 9: 7). Similar themes are maintained in the Talmud: 'The Holy One sits and nourishes both the horns of the wild ox and the ova of lice' (*Shabbat* 107b). And with regard to human affairs, 'He is occupied in making ladders, casting down the one and elevating the other' (*Genesis Rabbah* 68.4).

The New Testament similarly attests God's intimate involvement in all aspects of existence. Best known, perhaps, are the words of Jesus: 'Are not two sparrows sold for a penny? And not one of them will fall to the ground without your Father's will. But even the hairs of your head are all numbered' (Matthew 10: 29-30). God's reign extends over worldly authorities: 'Let every person be subject to the governing authorities. For there is no authority except from God, and those that exist have been instituted by God' (Romans 13: 1). And Christ, as 'Lord of Lords and King of Kings' (Revelation 17: 14), will in the end subject all nations to himself.

The Qur'an, too, emphasizes God's universal providential activity:

> Allah is He Who raised up the heavens without any pillars that you can see…. He it is Who spread out the earth and made therein firmly fixed mountains and rivers, and of fruits of every kind He has made pairs. He causes the night to cover the day. In all this, verily, are Signs for a people who reflect.
>
> (13: 2-5)

The theme of providence is taken up, in varying degrees, by the early Fathers and theologians of the Christian Church. Their reflections are mainly inspired by Scriptural testimony, but also include themes and references derived from the Greek philosophers. According to Irenaeus, for example:

> God does… exercise a providence over all things…. And, for this reason, certain of the Gentiles, … being moved, though slightly, by His providence, were nevertheless convinced that they should call the Maker of this universe the Father, who exercises a providence over all things, and arranges the affairs of our world.
>
> (*Against Heresies*, 3.25.1)

Augustine, however, gives by far the fullest account of providence to be found in the ancient Church. In *The City of God*, he paints a grand picture of the cosmic drama, beginning with the creation and the Fall, first of Satan and his angels, then of Adam and Eve, and culminating in the new heavens and the new earth, as the City of God and the earthly city each attain their appointed destinies in heaven and hell respectively. While the main emphasis is on God's redemption of humanity through Israel, Jesus Christ and the Christian Church, God's providence is involved in the affairs of pagan nations as well:

> The one true God, who never permits the human race to be without the working of His wisdom and His power, granted to the Roman people an empire, when He willed it and as long as He willed it. It was the same God who gave kingdoms to the Assyrians and even to the Persians.
>
> (*The City of God*, bk 5, ch. 21)

The main themes of Augustine's treatment survived intact through the Middle Ages and into the post-Reformation period, though his doctrines of grace and predestination remained controversial (see Augustine §§6, 10). Providence was often considered under the three headings of conservation (or 'sustenance'), concurrence and governance. The first two of these represent metaphysical aspects of God's support of his creatures; he both sustains them in existence and 'concurs' (or cooperates) with all of their activities, so that nothing in the world takes place without the exercise of divine power (see Creation and conservation, religious doctrine of §5). Governance, on the other hand, has to do with God's specific direction of worldly events to serve his purposes; it is primarily on this topic that problems arose in the modern era.

2 Post-Enlightenment issues and problems

For a variety of reasons, the Enlightenment was characterized by a general aversion to the miraculous, sometimes supported by philosophical arguments purporting to show either that miracles are impossible or that it is impossible in principle for human beings to ascertain that a miracle has occurred. Given this aversion, which found expression first in deism and then in various forms of liberal theology, it became quite problematic to speak of divine intervention in worldly affairs. This in turn makes it very difficult to see divine providence as manifested in particular occurrences. God's conservation and concurrence are entirely general in nature, and cannot serve to pick out some events as providential in contrast with others. So if God cannot in any way intervene to shape the course of events in one direction rather than another, there is a genuine question about the significance of any claim to 'see God at work' in specific events. Religious faith, on the other hand, cannot well be sustained without some sense of the active working of God. But with a ban on 'realistic' talk of divine intervention, identifying 'God's work in the world' tends to become an entirely subjective matter, lacking not only in public verification but even in publicly accessible meaning.

A second development is found in the tendency during the eighteenth and nineteenth centuries for the doctrine of providence to be closely associated or even identified with the belief in historical optimism and inevitable progress. This may be in part a reflex from the first development mentioned above. If we cannot with any confidence identify specific events as manifestations of divine governance, where else can we hope to see

providence except in the shape and direction of the human story as a whole? But the tendency was also nourished by the general optimism of the Enlightenment, and later by the growth of evolutionary interpretations of history. Doctrines of historical optimism and inevitable progress, however, have nearly enough been refuted by the empirical facts of history in the twentieth century. And to the extent that belief in divine providence was associated with these doctrines, it suffered a blow from which it has not yet recovered.

Yet a third development in recent thought about providence is the increased concern, among both critics of religion and believers, with the problem of evil (see Evil, problem of). The problem of evil is certainly not a new one; it was used against the Stoics by the Epicureans and against the early Christians by the Marcionites and later by the Manicheans (see Manicheism). Nevertheless, it is undeniable that the preoccupation with this problem has increased, though the reasons for the increase are not entirely clear. No doubt the tendency noted in the previous paragraph to identify belief in providence with historical optimism, has played a part. The horrendous evils of the twentieth century - the two World Wars and the Holocaust, in particular - have also played a role, though it is not clear that human life on average has been worse for people of this century than for those of earlier epochs. It may be, also, that our perception of the real possibilities, through technology and medicine, of a better life for human beings has made us less tolerant of the deplorable conditions in which very many human beings have lived and still live today. In any case, it is evident that many appeal to the world's evil as a demonstration that belief in God and in providence - at least, as traditionally conceived - is no longer viable. Many theologians and philosophers of religion are more willing than their counterparts in earlier times to consider limitations on God's control over worldly events in order to lessen the directness of his involvement in and responsibility for evil.

3 The resources of providence: five options

A crucial question for any doctrine of providence concerns the resources that are available to God as he exercises his controlling oversight. The key variables here are the power of God, God's knowledge (especially his knowledge of the future), and the nature of human freedom. The views of providence that adhere generally to traditional Western theism, however, do not differ significantly concerning the power of God. (Process theism, as we shall see, is an exception here.) All the major views accept that God's power is limited only by what is logically possible, and perhaps by ethical constraints inherent in the divine nature (see Omnipotence §§1-3). This means that none of these views finds the notion of divine intervention in the world fundamentally problematic, though theologies will differ with respect to the sorts of divine interventions that actually occur. But there are serious disagreements concerning the nature of human freedom and divine knowledge (see Omniscience §§3-4). Here we survey five different views, beginning with the one which affords the highest degree of divine control over the world.

Theological determinism, or 'Calvinism' (so called because of its association with Calvin (§§3-4), though it was held already by Augustine and probably also by Aquinas), holds that everything that happens, with no exceptions, is efficaciously determined by God in accordance with his eternal decrees. This means that God's control over events is absolute; there is no non-logical limitation on the states of affairs God is able to bring about. Calvinists do usually affirm human freedom, but only in a compatibilist sense. And God is able to know the future comprehensively simply by knowing his own intentions.

The theory of divine middle knowledge is also known as Molinism, after Luis de Molina (§§1-3), who first propounded it (see Molinism). The key idea of Molinism is the attribution to God of the knowledge of a certain class of propositions, now usually called 'counterfactuals of freedom'. Such counterfactual propositions state, concerning a particular free creature, what that creature would do in a particular situation of (libertarian) free choice with which it might be confronted. According to Molinism, God knows all the counterfactuals of freedom concerning all actual and possible free creatures. Thus, the fact that the creature is endowed with libertarian freedom constitutes no limitation on God's ability to anticipate the creature's actions; God merely consults his knowledge of the relevant counterfactuals in order to know exactly what the creature would do in any circumstance in which it might find itself. And this is of immense benefit with regard to God's providential governance of the world: God can survey in advance all of the possible scenarios for creation (all the 'possible worlds'), and select the very one which best fulfils his creative purposes. And once the decision is made, the exact fulfilment of God's plan is guaranteed; the necessity for any risk-taking on God's part is eliminated entirely. God's control is not as absolute as with Calvinism, for God is limited by the counterfactuals of freedom, which are not

under his control. But given the counterfactuals, God is able to guarantee the actualization of the very best ‘feasible world’.

The theory of ‘simple foreknowledge’ agrees with Molinism that human beings possess libertarian free will, and also that God has comprehensive knowledge of the future. But it does not accept that God possesses middle knowledge, knowledge of the counterfactuals of freedom. (Many adherents of simple foreknowledge deny that there are any true counterfactuals of freedom.) God’s knowledge of the actual future is usually regarded as a kind of ‘direct vision’ - God ‘sees’ it as if in a telescope or a crystal ball.

The view that is coming to be known as ‘free-will theism’ differs from the simple foreknowledge theory by denying that God has comprehensive knowledge of the future. Free-will theism leans heavily on the arguments purporting to show that infallible foreknowledge of future free actions is impossible. God, however, has comprehensive knowledge of the world’s past and present, as well as knowledge of the dispositions, tendencies and so on of free agents. Furthermore, God is able to know many important things about the future on the basis of his own intentions, which in key respects are not contingent on the decisions of creatures. Nevertheless, God is not always able to guarantee in advance the results that will follow from his own actions and the situations he chooses to create; thus, for free-will theism, providence involves a genuine element of divine risk-taking.

The final option to be considered is process theism, a contemporary view which draws heavily on the philosophy of A.N. Whitehead (see Process theism; Whitehead, A.N. §4). Process theism agrees with free-will theism that divine foreknowledge is necessarily limited by creaturely freedom. But it deviates sharply from all versions of traditional theism in its conception of God’s power and activity. The process view of divine power may be summarized succinctly by saying that such power is always persuasive and never coercive. God is at all times attempting to persuade humans and other creatures to follow his way, by presenting to them his ‘initial aim’ for them, the ‘direction’ in which he wants them to go so as to realize rich and intense values in a harmonious fashion. But he does not, because he cannot, compel any created being to do his will, and so the actual course of events depends on how finite beings respond to God’s persuasion. This means that God’s ability to secure the fulfilment of his plan is actually very limited in comparison with that posited by all the other theories considered - and also in comparison with what seems to be presupposed in the Jewish, Christian and Muslim Scriptures.

4 Assessing the options

Clearly Calvinism affords God the maximal degree of control over worldly affairs. (It is noteworthy, however, that it does not in fact accord to God any greater power than he possesses according to Molinism, simple foreknowledge, or free-will theism.) The price to be paid for this absolute control is extreme difficulty in accounting for the world’s evil. If God has by his own decree ensured the existence of all the evil and sin that there is, how can human beings justly be held responsible for it? And how can God himself avoid being responsible for evil? How, indeed, is it intelligible that God has chosen to bring about sin and moral evil, and has then assumed towards what he has knowingly and deliberately chosen an attitude of utter, implacable hostility? It seems likely that there is no rationally comprehensible answer to these questions; Calvinists themselves frequently say that the relationship between God and evil is an impenetrable mystery.

Molinism, unlike Calvinism, accepts the existence of libertarian freedom and thus avoids the most severe of Calvinism’s difficulties over evil. At the same time, it manages to ascribe to God a degree of providential control that is second only to Calvinism and is probably the greatest control possible if determinism is rejected. There are, however, serious metaphysical difficulties involved in the postulation of counterfactuals of freedom and middle knowledge. And Molinism does not remove all the sting of the problem of evil, for each instance of evil that occurs is one that God has specifically ‘planned, ordered, and provided for’ (Freddoso 1988: 3; in Molina 1592). So one is led to the difficult assertion (though one that is often enough made) that each and every instance of evil that exists is necessary for the existence of a ‘greater good’ (or the prevention of a greater evil) that God could not bring about without the evil in question.

The arguments concerning the compatibility of comprehensive divine foreknowledge and libertarian free will are well known and highly controversial. Somewhat surprisingly, these arguments do not have any important bearing on divine providence once middle knowledge has been given up. The reason for this is that simple foreknowledge does not contribute anything to God’s providential control over the world beyond what he would have without it.

To see this, consider the following argument: suppose God possesses comprehensive knowledge of the state of the earth as of some future time *t*. The state of the earth at *t* presupposes the entire causally relevant past history leading up to *t*. Now suppose that God decides, on the basis of his knowledge of the earth at *t*, to intervene in the earth's history at some earlier time $t - n$. A little reflection shows this scenario to be incoherent. For what God knows is, by hypothesis, the actual history of the earth leading up to *t*; to suppose that, on the basis of that knowledge, God intervenes in such a way that the actual history consequent upon the intervention is different from the history God knows to be actual makes no sense. We may conclude from this that it is impossible that God should use foreknowledge derived from the actual occurrence of future events to determine his own prior actions in the providential governance of the world. If simple foreknowledge did exist, it would be useless. (The same argument applies to divine timeless knowledge of the future, where this is not accompanied by middle knowledge (see Eternity).)

So free-will theism, simple foreknowledge, and divine timelessness can be treated together. All these views entail what may be termed a 'risk-taking' view of providence; they entail that when God makes decisions that depend for their outcomes on the responses of free creatures, his making of those decisions is not guided by a prior knowledge of the outcomes. This does something to mitigate the problem of evil, in that it need not be assumed that God has specifically 'planned, ordered, and provided for' each instance of evil that actually occurs. It also, to be sure, means that God's control over events is somewhat less direct and pervasive than theology has often assumed. Whether these consequences are acceptable is an important question for theology.

The chief appeal of a process view of providence (over and above the possible attractiveness of a God who is wholly non-coercive) lies in the fact that it virtually disposes of the problem of evil: God cannot properly be said to permit the world's evil, because he has no power to prevent it from occurring. The price of this is a virtual abandonment of the view (central to all historic conceptions of providence) that God is in control of what happens in the world. Whether this is acceptable is, once again, an important question, of fundamental religious as well as theological import.

Prudence

The word 'prudence' is used in several ways in contemporary English, and its different philosophical senses to some extent reflect that variety. Traditionally, prudence is the ability to make morally discerning choices in general; but the term is also used to denote a habit of cautiousness in practical affairs; most recently, attempts have also been made to identify prudence with practical rationality, perhaps even with the pursuit of the agent's own interests, without any specifically moral implications.

1 Prudence as a cardinal virtue, and contrasted with rashness

In its most traditional sense, 'prudence' translated the Latin *prudentia*, which in turn was the technical translation of Aristotle's *phronēsis* (*Nicomachean Ethics*) (see Aristotle §23). Most contemporary English-speaking philosophers translate *phronēsis* as 'practical wisdom', and discussion of this latter topic will reveal much that traditionally was meant by 'prudence'.

Prudence was considered a virtue of the practical intellect (see Virtues and vices §3). That is to say, it consisted in an admirable intellectual skill in practical, as distinct from theoretical, matters. The details of this, in Aristotle and in Aquinas, are a matter of controversy, but in general it can be said that the prudent person has to have both an understanding of what human fulfilment is and an ability to perceive which action, here and now, can contribute to living a life of human fulfilment (see Eudaimonia).

The intellectual virtue of prudence presupposes other intellectual skills. A successful doctor needs good diagnostic abilities in order to see what is wrong with a patient, a practical knowledge of the treatment appropriate to this patient here and now, and perhaps also the ability to plan ahead for various stages of a long-term treatment. These skills in themselves were thought to be morally neutral; they might equally well characterize a doctor intent on making a fortune as a highly effective practitioner. Specific to prudence is the ability to see how these medical skills can fit into a fulfilled human life, and hence how their use can be morally significant, not simply technically or financially successful (see Morality and ethics §2).

Prudence was traditionally contrasted with three other virtues: justice, fortitude and temperance. The latter two were thought to be 'moral' virtues, as distinct from prudence, which is an intellectual virtue. The term 'moral virtue' is confusing, since prudence, too, is concerned with the moral significance of what one does. The phrase 'moral virtue' reflects Aristotle's term *ēthikēaretē*, which referred to admirable emotional dispositions in the realms of aggressiveness and desire (see Morality and emotions §3). Justice, on the other hand, was thought to reside not in the emotions (as the moral virtues do), nor in the intellect (as prudence does), but in the will. The prudent person would understand what is morally required in each situation; the just person is habitually willing to do what is morally required in giving each person their due.

These four virtues were called 'cardinal' virtues (from the Latin *cardo*, meaning 'hinge') because it was held that possession of all the more specific virtues, such as loyalty, kindness, courage and honesty, turned on the possession of these four. Indeed, Aquinas, like Aristotle, believed that one cannot have prudence without fortitude and temperance, because inappropriate emotional reactions to a particular situation would cloud one's intellectual grasp of what was morally required (*Summa theologiae* IIaIIae.47, IIaIIae.56).

The ability to grasp what is morally required in individual situations is sometimes explained as the ability to reason from general moral principles to particular cases. But the classical writers rather took the view that seeing which principle applies, and how it applies, is not a matter of argument, but, as Aristotle put it, a kind of perception (see Virtue ethics §6). Critics of a rationalistic bent have objected to this form of moral intuitionism.

Sometimes, rather than being considered as a cardinal virtue of great generality, prudence is conceived of as a particular virtue, contrasted with rashness. Thus, it might be prudent to insure one's house against fire, and prudent for the managers of a trust fund to invest in such a way that the participants in the fund were not exposed to speculative risks. Seen in this way, prudence is a particular virtue, and still belongs to the realm of ethics. On the other hand, 'prudent' is occasionally used in a more critical sense: to insist on prudence is to insist on playing safe on every possible occasion. If it is thought that some risks are reasonable, or even that it is morally required on occasion to take some risk, prudence in this last sense might even be a vice rather than a virtue.

2 Possible nonmoral senses

More recently, philosophers have used the term 'prudence' in ways which are quite different from those already discussed. Two separate contrasts are involved, which unfortunately are often confused. The first is that between the moral and the nonmoral; and the second is that between the agent's own interests and the interests of other people (see Egoism and altruism). Invoking the first contrast, prudential reasons for doing something are held to be different in kind from moral reasons. Invoking the second contrast, prudential reasons are said to be those involving the agent's own interests, rather than those of others. On these grounds, it is sometimes argued that egoism does not count as a theory of morality at all, since the reasons egoists would give in support of an action are reasons connected either immediately or in the longer term with the furtherance of their own interests, and hence are 'merely prudential'. Moreover, it does seem to be the case that we are inclined to criticize people more severely for failing in their duties towards others, even if these duties are duties of prudence, than we are to criticize for failure in prudence in respect of oneself. This thought leads to the suggestion that failure in prudence with respect to oneself, though it may be irrational, is not properly a moral fault at all.

There are problems with this overall view. First, it is not at all clear that prudential considerations are properly thought of as nonmoral. If to insure one's house is prudent, is that not a moral reason in favour of doing so? And in general, there might be some risks which it is simply morally wrong to take. Second, it is not clear that prudential considerations are restricted to the interests only of the agent. The trust fund manager has prudential duties to the participants in the trust, and it is surely reasonable to suppose that these are moral duties. Third, it is not obvious that one is subject to moral requirements only towards other people and not towards oneself as well; Kant, for example, held that one has moral duties to oneself just as much as to others, as indeed do most theories which lay stress on impartiality as an important feature of the moral (see Impartiality; Kantian ethics). But if this is so, then the distinction between self-regarding and other-regarding considerations does not coincide with the distinction between the nonmoral and the morally significant. At least part of the difficulty may stem from the fact that we ordinarily use the term 'prudence' in a variety of senses according to context, some closer to the older usage, others much less so.

Be that as it may, 'prudence' is often used in contemporary philosophy as equivalent to 'practical rationality', without any implications about moral significance. The prudent choice is that which, broadly speaking, furthers the agent's ends. The qualification is necessary because many writers have considered that we have to assume that agents formulate their decisions on the basis of full information, and do so without being influenced by such things as bias, malice or emotional stress. So it might appear that moral considerations have been reintroduced into the concept, thus bringing it closer to *phronēsis* and the medieval *prudentia*. Moreover, in default of an adequate characterization of the information and state of mind required for prudent choice, the practical usefulness of the concept is much lessened. For this reason other writers have been prepared to say simply that the only empirical basis for assessing persons' interests is to be found in the choices they actually make (see Rational choice theory). In this way, particular decisions may be assessed as irrational, and hence as imprudent, on formal grounds such as inconsistency, or being self-defeating, or being ill-adapted to stated ends; but criticism aimed directly at the content of such choices is excluded.

Theories of nonmoral rational choice themselves present problems, especially in relation to political philosophy, in which consideration has to be given to the different preferences of different individuals. This part of the modern discussion of prudence touches on some of the issues dealt with in older discussions of justice. The traditional definition, 'a willingness to give each person their due', of course does not answer the question how one is to discover what is due to different people, nor the further question whether it is possible to give a rational account of the 'best' way of reconciling conflicting preferences. These are just the problems which recent accounts of rational choice theory try to investigate.

Pseudo-Dionysius (*fl. c.* AD 500)

'Pseudo-Dionysius' was a Christian Neoplatonist who wrote in the late fifth or early sixth century and who presented himself as Dionysius the Areopagite, an Athenian converted by St Paul. This pretence - or literary device - was so convincing that Pseudo-Dionysius acquired something close to apostolic authority, giving his writings tremendous influence throughout the Middle Ages and into the Renaissance.

The extant four treatises and ten letters articulate a metaphysical view of the cosmos, as well as a religious path of purification and perfection, that are grounded in the Neoplatonism developed in the Platonic Academy in Athens. Although this strand of Neoplatonist thought, in contrast to that developed at the school in Alexandria, was deliberately pagan in its religious orientation, Pseudo-Dionysius used its conceptual resources (drawing especially on Proclus) to give precision and depth to the philosophical principles of a Christian world view. Cardinal points of Pseudo-Dionysius' thought are the transcendence of a first cause of the universe, the immediacy of divine causality in the world and a hierarchically ordered cosmos.

1 The works: character and origin

Pseudo-Dionysius' works clearly reflect the late Neoplatonism of the fifth and sixth centuries, creatively modified in accordance with fifth-century Christian ideas and commitments. These facts belie the author's claim to be the disciple of Saint Paul who is described in Acts 17: 16-34 as an instantly converted member of an Athenian judicial body (*areopagos*) asked, by certain Epicurean and Stoic philosophers, among others, to judge the acceptability of Paul's preaching in Athens. The scholarly case against Pseudo-Dionysius' assumed identity was first made by Lorenzo Valla in 1457 and was publicized by Erasmus in 1504. Pseudo-Dionysius' real identity, however, remains unknown, despite continued debate during the sixteenth and seventeenth centuries and renewed scholarly investigation since the end of the nineteenth century.

The range of possible dates for authorship of the corpus is bounded at its early end by the conclusion of Proclus' career in AD 485. This dating is confirmed by Pseudo-Dionysius' appeal to parts of the Christian liturgy and to certain doctrinal formulae current in the late fifth century, and by his adaptation of late fifth-century Neoplatonist religious rites. The latest possible date is set by the earliest unmistakable citation of Pseudo-Dionysius' works, by Severus of Antioch between AD 518 and 528.

A translation into Syriac by Sergius of Reshaina (d. AD 536) made possible the rapid spread of Pseudo-Dionysius' ideas throughout the Syrian Christian centres of learning. Armenian and Arabic translations have also been found, and there is some evidence for Pseudo-Dionysius' influence in the Islamic realm. Despite these successes, however, the pseudonymous philosopher's claims to authority were not uncontroversial; nor was it clear that his views about the Trinity or the nature of Christ were orthodox. Eventual acceptance on both counts required repeated defences, for example by John of Scythopolis and by Maximus Confessor.

Despite a florid or seemingly even obscurantist style, Pseudo-Dionysius shows himself in his works to be a serious philosopher, struggling against limitations of language and wrestling with the paradoxicality of metaphysical propositions about God, creation, cosmic order and so on. His systematic intent shows not only in his philosophically most important work, *Peri theiōn onomatōn (On the Divine Names; Latin, De divinis nominibus)*, but also in his grand project. As he explains, this project commences with some treatments of the nature of God and the supra-sensible order insofar as they are accessible to us only with the aid of revelation. (These works are not extant and may never have been finished.) Then, relying more on human reason and thereby descending, as it were, in the cosmic hierarchy, Pseudo-Dionysius undertakes to treat God metaphysically in *Peri theiōn onomatōn*. From this standpoint he descends still further, treating God and the cosmic order insofar as they can be understood through sensible creatures, more distant manifestations of God that allow a kind of metaphoric understanding of their divine cause. Such objects Pseudo-Dionysius thinks of as symbols, and the two extant treatises *Peri tēs ouraniās hierarchiās (On the Celestial Hierarchy; Latin, De coelesti hierarchia)* and *Peri tēs ekklēsiastikēs hierarchiās (On the Ecclesiastical Hierarchy; Latin, De ecclesiastica hierarchia)* can be considered partial presentations of what he calls 'symbolical theology'.

Having reached the lowest point in the cosmic order, physical things and human religious institutions (whose

rituals facilitate the metaphoric understanding of God), Pseudo-Dionysius now tries to recapitulate and complete the cognitive endeavour to reach God. He does this by exposing the limitations of the various sorts of positive knowledge he has outlined in the foregoing treatises. In this way he means to insure his reader's return to God after the descent to the level of creatures. He describes the method by which this perspective is achieved in his *Peri mystikēs theologiās (On Mystical Theology; Latin, De mystica theologia)*.

2 Doctrine and context

The outline of Pseudo-Dionysius' philosophical project indicates a basic Neoplatonist principle on which his system rests: all finite things 'proceed from' (that is, are caused by) a being that is transcendent, infinite and perfect, and they eventually 'return to' this being since their fulfillment lies in closeness to it and they are sustained by it for this end. This cosmic cycle of procession and return is the pattern according to which the first cause, or God, exercises its originative capacity and, so to speak, manifests itself through a world of creatures (see Neoplatonism).

According to its classic presentation by Neoplatonists from Plotinus through Proclus, the cosmic cycle actually involves three stages. Prior to the stages of procession and return, there is a first stage of 'immanence' in which the effects abide in their cause, being in a certain sense contained in the cause prior to their being caused. In line with that traditional theory, Pseudo-Dionysius speaks of things in the world as being 'contained beforehand' in their cause 'in a higher way', that is, as initially undifferentiated. However, by focusing on and developing the idea of the first stage, he makes one of his most original contributions to Neoplatonist metaphysics.

To understand this, one must first note two problems within Neoplatonism. First, there is a tension between the claim that the first cause is absolutely simple, containing its effects in some wholly undifferentiated way, and the claim that it does in some way really contain these effects. Second, if the first cause is radically different from its effects in virtue of its simplicity and perfection, and if its causality consists in making things like itself (bringing things to 'participate' in its perfection), how can it actually give rise to effects in the world, since they are quite different from it in nature? Exponents of classical Neoplatonism tend, to one degree or another, to meet these difficulties by supposing intermediate levels of reality between the first cause and its ultimate effects in the world. These 'hypostases' are causally prior to things in the world of nature but are causally dependent on the first cause, and they are supposed to mediate causally between the first cause and its ultimate effects. Pseudo-Dionysius reverses this multiplication of intermediary hypostases, which, one might argue, reaches excessive proportions in later Neoplatonists such as Iamblichus and Proclus. He does so by further developing the notion of the first cause's precontainment of its effects. In *Peri theiōn onomatōn*, he argues that the predicates that would be construed in classical Neoplatonism as signifying intermediate hypostases in fact simply designate the first cause itself, considered with respect to effects that it is capable of producing in virtue of its intrinsic perfection.

This account of how the first cause causes things in the world is connected with two other salient Dionysian doctrines. Classical Neoplatonism had generally characterized the first, completely simple and perfect cause as 'the One', and had claimed that this cause of all things in some radical sense transcended being itself. Though Pseudo-Dionysius has often been taken to adhere to this claim that the first cause is 'beyond being', he in fact contends that the first cause is beyond the being of anything finite, even beyond the general sort of being that it can bestow on finite things; but it itself is perfect, infinite being. Pseudo-Dionysius seems to think that this characterization, in contrast to the classical Neoplatonist characterization, accords the first cause a kind of richness that explains how it can indeed be transcendently simple and yet in some sense contain all its effects. Second, Pseudo-Dionysius develops the Platonist idea that the first cause is the good itself. His famous principle, 'The good is such as to diffuse itself', indicates that it is in the very nature of the first cause, on account of its intrinsic perfection, to give rise to the variety and plurality of finite things in the world.

With regard to the return of finite beings to their source, Pseudo-Dionysius complements the ontological conception of a comprehensive hierarchy of beings of various degrees of perfection with an epistemology that stresses gradual cognitive ascent. The finite mind approaches the infinite source by climbing from an understanding of one level in the hierarchy to an understanding of the next. This ascent, which both requires and furthers moral and spiritual purification, finally ends in a state of unification with God that Pseudo-Dionysius describes as an 'inactivity of all knowledge', or a 'knowing beyond the mind', since in this state all particular knowledge must be left behind. Progressive illumination thus culminates, paradoxically, in the 'mysterious

darkness of unknowing'. Achieving this state requires ultimately a kind of radical psychic break with ordinary ways of thinking and acting - a spiritual ecstasy.

3 Philosophical influence

Pseudo-Dionysius had a substantial influence on Christian spirituality as well as on medieval and Renaissance philosophy. The influence of his ideas about the spiritual life can be seen most clearly in the writings of medieval and Renaissance mystics who echo some of his pronouncements about the soul's union with God (see Mysticism, history of). His method of apprehending God by negating positive knowledge - and ultimately seeing God as beyond both affirmation and negation - has appealed to the mystical temper. This method (*via negativa*) must be distinguished, however, from a mystical approach to God, if by that is meant either some sort of actual convergence of the enraptured soul with divinity or a non-intellectual approach (see Mysticism, nature and assessment of; Negative theology).

Pseudo-Dionysius' particular philosophical influence is especially marked and important in the Latin West. Its first phase comprises his entry into Western thought in the Carolingian period, via a translation into Latin by Hilduin in 832, and his appropriation by Eriugena, who retranslated the works in 862 and extended his ideas in the direction of metaphysical monism. The second phase of influence occurs as part of the rebirth of learning in the twelfth century, and can be seen in such diverse philosophers as Hugh of St Victor, Isaac of Stella and Peter Lombard. His aesthetics (a chapter of *Peri theiōn onomatōn* is devoted to the predicate 'beauty') made its mark by inspiring, directly or indirectly, Abbot Suger's programme for a new architecture, the Gothic, that would lead the soul upward via sensible reality.

The third phase of influence lies in Pseudo-Dionysius' formative effect on some of the greatest philosophers of the thirteenth century: Robert Grosseteste, Albert the Great, Thomas Aquinas and Bonaventure. These philosophers (except Bonaventure) wrote substantial commentaries on Pseudo-Dionysius; Albert and Aquinas especially used their detailed knowledge of Dionysian texts to assimilate and then develop Platonist principles, making them foundational for their metaphysical systems. Finally, Pseudo-Dionysius' influence appears in the Renaissance as a factor in the revival of interest in Platonism in general. Pico della Mirandola and Marsilio Ficino, affirming the genuineness of Pseudo-Dionysius' claims to authority, see him as the exemplary Christian Platonist and hence as the exemplary philosopher.

In general, Pseudo-Dionysius appeals to medieval and Renaissance philosophers because he seems to them to be leading the way in regard to a common enterprise: the adaptation of Platonist philosophy to the purposes of monotheistic metaphysics. His ideas of creative goodness, creation against the backdrop of nothingness, the metaphysical primacy of being, the nature of evil as privation and the orderliness of the cosmos in terms of a hierarchy of perfection give his writings exceptional philosophical importance, an importance far beyond what they could have had merely by virtue of their presumed authority.

Pseudo-Grosseteste (*fl. c.*1265-75)

'Pseudo-Grosseteste' is the name given to the unidentified author of a philosophic encyclopedia written in England in the third quarter of the thirteenth century. Like other encyclopedias of that time, the Summa philosophiae (Summa of Philosophy) marshals an astonishing array of facts, principles and arguments in every field of philosophic interest, from accounts of truth or cosmologies through analyses of rational and animal souls to the properties of minerals. The Summa is distinguished not by its range of interests, but by its clear sense of its own purposes. The author intends to arrange the history and the particular doctrines of philosophy within a hierarchy built according to Augustinian principles.

To Robert Grosseteste, as to many other ancient or medieval authors, medieval scribes attributed a number of works that modern scholarship now judges spurious. Among works falsely attributed to Grosseteste there are a complete exposition of the Gospels, fragments of a summa of theology and two large-scale summaries of philosophy, one entitled *Summa philosophiae (Summa of Philosophy)* and the other *Compendium philosophiae (Compendium of Philosophy)*. The *Compendium* was quickly returned to its real author, the twelfth-century polymath Dominicus Gundissalinus, but the *Summa* has found no other author, and so it is still assigned to a 'Pseudo-Grosseteste'. It is the author of this work, and only of this work, who is treated here.

The *Summa philosophiae* cannot be by Grosseteste because it refers to an event, the death of Simon de Montfort, that occurred twelve years after Grosseteste's own death. There is little other evidence to place it precisely. It seems on internal evidence to have been written during the third quarter of the thirteenth century, probably between 1265 and 1275. Most scholars find traces of English authorship. There are citations to Alfred of Shareshill and perhaps to John of Salisbury, if it is he who is named 'John the Peripatetic'. More significantly, the *Summa* shows striking affinities with the *Opus majus* of Roger Bacon, to whom it defers on some disputed points of physical doctrine. Curiously, the *Summa* does not mention Grosseteste himself. It should also be noticed that the genre of the naturalist's encyclopedia was quite popular with English authors in the thirteenth century, attracting such notables as Alexander Neckham, Bartholomew the Englishman and Thomas of York.

The *Summa* also invokes a large number of other authors, ancient, patristic, and medieval. The largest number of references is to Aristotle, followed at some distance by Plato, Averroes, Avicenna and Augustine, but a simple count of citations is misleading. The principal philosophical authority here is not Aristotle, but Augustine. On any number of disputed points, the *Summa* sides with Augustine against Aristotle or the Aristotelians. For example, the proofs for the existence of God are not proofs from motion or causality, but from the necessity for an eternal first truth. The pattern of argument here is to be found in Augustine's *Soliloquia (Soliloquies)* and *De libero arbitrio (On Free Choice of the Will)*. Again, in its division of matter the *Summa* allows for spiritual matter as an individuating principle in immaterial beings. At these and other points, the author of the *Summa* shows himself on the side of contemporary Augustinians. This is confirmed in the references to medieval authors. The *Summa* cites approvingly Alexander of Hales and Albert the Great, both of whom it includes in its history of 'philosophy'. Alexander is the great authority among the Franciscans, and he relies throughout his work on Augustine. Albert is taken by the *Summa* either as a teacher of natural philosophy or as an eclectic thinker open to Neoplatonic doctrines. There are allusions to the teachings of Thomas Aquinas, but they are hardly approving. Indeed, the author of the *Summa* singles out distinctively Thomist positions on several occasions for sharp criticism.

The *Summa* is divided into nineteen Books, a number also adopted by other encyclopedias of the thirteenth century. The Books may be arranged thematically into four groups: an introduction on the nature of philosophy and its relation to theology (Book 1); the principles of being and knowledge (Books 2-6); God and the creation in general (Books 7-9); and specific creatures, from the immaterial to the most material (Books 10-19). The last group is by far the longest and most detailed. It offers, for example, careful analyses of the types of soul, the operations of light, the properties of the elements, meteorological phenomena and minerals.

Psychē

Conventionally translated 'soul', psychē *is the standard word in classical Greek for the centre of an animal's, and especially a human being's, 'life'. In its earliest usage (in Homer)* psychē *is a breath-like material persisting after death as a mere ghost. Its precise reference to the locus of thought and emotion only began under the influence of philosophy. From the beginning of the fourth century* BC *it became normal to pair and contrast* psychē *with 'body' (*soma*). The term generated sophisticated discussions. Leading questions include: Is* psychē *immortal? Is it corporeal or incorporeal? What are its parts or functions?*

Before philosophy there was no single Greek term for the mind or for the body. In Homer *psychē* refers to the life or ghost of a person rather than to the mind as such. Homer uses other terms for the location of thought and emotion, probably because *psychē* was taken to comprise *all* the powers a living person loses at death: Homer's disembodied shades retain the characters and histories of their embodied lives. By 500 BC Pythagoras had become famous for rejecting the Homeric Hades and for teaching the transmigration of the same *psychē* into a succession of bodies, animal as well as human. Around the same time Heraclitus treated *psychē* not only as the source of life but also as something to which the predicates 'wisest and best' can apply. Gradually the term gained wider currency as a way of referring to the self or personality. Socrates invokes this usage in Plato's *Apology* when he exhorts the Athenians to subordinate concern for their bodies to the care of their *psychē*.

Sustained reflection on *psychē* began with Plato. In his *Phaedo*, although the *psychē* animates the body, that is not its best or primary function. Incorporeal and immortal, the *psychē* is unavoidably tainted by incarnation. The task of philosophers is to detach themselves from the distractions of the body in preparation at death for a return of the *psychē* to a discarnate state of purity and wisdom. In this dialogue sensual desires originate only in the body but a thoroughly impure *psychē* will identify with the body instead of valuing intellectual goods (see Plato §13). Plato subsequently modified this doctrine. In his *Republic* IV, and repeatedly thereafter, he divides the *psychē* into three components - rational, spirited or competitive, and appetitive; this last component (and not the body itself) is the drive for instant sensual gratification. Plato's principal ground for this tripartition is the need to explain how a person can be simultaneously subject to conflicting desires. On this model of the *psychē*, each component has its own objectives. In a well-integrated *psychē*, the subordinate components perform their proper functions (of facilitating a person's embodied life) under the rule of reason (see Plato §14).

Plato's moral psychology had a decisive influence on all the subsequent philosophical tradition. Later philosophers, however, paid closer attention to the biological functions of *psychē*. For Epicureans and Stoics, the *psychē* is a physical part of the living being, centred in the chest and distributed from there to the organs of the body (see Epicureanism §§12-13; Stoicism §3). For Aristotle (§§17-19), it is not a physical part but the 'form' or 'active functioning' of the body's organs, except in the case of intellect (see Nous) which has no bodily organ. Plato had located the rational component of *psychē* in the head, but most philosophers, mistaking the functions of the cardiovascular system, favoured the chest or heart as its location. These errors continued even after the nervous system was identified in the third century BC. The first theorist to relate psychology to the most up-to-date physiology was Galen (§2), writing in the second century AD.

In spite of these errors post-Platonic philosophers did work of lasting value in theorizing about *psychē*. Taking the human *psychē* to be an assemblage of vital functions, Aristotle analysed these, starting with the 'nutritive' (common to all living beings including plants) and ending with the 'intellectual' (peculiar to human beings). He is at his most effective, perhaps, in identifying the causal components of action: desire is stimulated by sense perception or 'imagination' (*phantasia*), and then intellect (in its practical function) works out the means to achieve the desired end (see Aristotle §§20, 23-4).

Epicurus' theory of *psychē* is grounded in his physics. Being an aggregate of fine and highly mobile atoms, the *psychē* depends upon embodiment in order to exist, and cannot survive the body's dissolution. Although the motions of atoms underlie all mental phenomena, Epicurus saw no difficulty in ascribing causal agency to thought and desire. According to Lucretius, Epicureans held that the random swerve of a mind's atoms frees it from mechanistic determinism.

The Stoic doctrine of *psychē* is also anchored to basic physical postulates. The 'active principle' of the Stoic universe is 'breath' (see Pneuma) permeating everything, and the 'breath' permeating animals and human beings is their *psychē*. Unlike Aristotle, the Stoics did not attribute *psychē* to plants. In their philosophy *psychē* is the life principle of animals (creatures capable of perception and purposive motion) and more particularly of human beings, who have the additional faculties of reason and 'assent' (saying yes or no to their occurrent thoughts and impressions). In contrast with other philosophers, the Stoics ascribed rationality to the human *psychē* in its entirety. But a rational *psychē* can act irrationally through error, and it can experience conflict of desires by oscillating between one judgment and another (see Stoicism §19).

In the Neoplatonism of Plotinus (§4), *psychē* is a principle that mediates between the higher reality of 'intelligible being' and the physical world ('nature'). This doctrine applies both to the *psychē* of individual beings and to that of the world. The world-soul generates the physical world by its apprehension of intelligible reality. The souls of human individuals, even when embodied, do not 'descend' completely to the physical world. They live at two levels, one contemplative and immortal, the other mortal and engaged with embodied life. Apart from these ideas Plotinus treated numerous mental phenomena with great subtlety in his long treatise, *Problems of the Soul (Enneads)* IV.

Although discussions of *psychē* centre primarily on the vital powers of human beings, Plato and the Stoics as well as Plotinus attributed *psychē* to the world at large. Aristotle did not adopt this view in *On the Soul*, but he agreed with them in making the heavenly bodies ensouled. Only Epicurus restricted the scope of *psychē* to terrestrial creatures.

Psychoanalysis, methodological issues in

Philosophers have subjected psychoanalysis to an unusual degree of methodological scrutiny for several interconnected reasons. Even a cursory look at the Freudian corpus reveals a slender base of evidence: eleven 'case histories', including those published jointly with Breuer. On the other hand, the theoretical claims have broad scope: all psychopathology can be traced to repressed sexuality. Further, Freud and his followers have disdained the most widely accepted means of establishing theories - experimental confirmation - while allowing themselves to appeal to such apparently dubious sources of support as dream interpretation, literature and everyday life. Together, these factors conjure a picture of a 'science ' with a large gap between theory and evidence that has not and cannot be filled by solid data.

The central methodological question about psychoanalysis is whether there is now or ever has been any evidence supporting its truth. Popper rejected psychoanalysis as a science on the grounds that there could be no possible evidence against it which could test its truth. More recently, Grünbaum has objected that there are serious logical difficulties with appealing to cures as evidence of truth. Grünbaum and others have attacked both the theory of dreams and the use of dream interpretation as evidence. Sulloway and Kitcher have argued that several tenets of psychoanalysis were supported by their nineteenth-century scientific context, particularly certain aspects of Darwinian biology, but that those crucial supports have been eroded by later scientific developments. Eysenck and Wilson have examined experimental results that have been offered in support of various claims of psychoanalysis and rejected them as inadequate to establish any specifically psychoanalytic claims. By contrast, Glymour (and others) have explained how even single case histories could provide evidence in favour of psychoanalysis. Other philosophers have argued that psychoanalysis is continuous with 'common-sense' psychology and is supported by the continual reaffirmation of the essential correctness of common-sense psychological prediction and explanation.

1 Popper and Grünbaum

Two influential critics of psychoanalytic methodology have been Sir Karl Popper and Adolf Grünbaum. Although Popper did not publish his objections to psychoanalysis until 1962 (see Popper 1963), they were well-known in philosophical and psychoanalytic circles for many years before that. Dissatisfied with attempts to distinguish sciences as 'speculative' versus 'observational', he proposed a different approach to the question of demarcating the 'scientific' from other types of theories. In his view, what distinguished theoretical systems, dividing them into the 'scientific' and the 'pseudoscientific', was their 'refutability' or 'falsifiability'. For any scientific theory, there must be some possible, but not actual, observation that would be inconsistent with the claims of that theory; if a 'theory' is compatible with any possible observation whatsoever, then that theory is mere 'pseudoscience'.

Along with Marxism, psychoanalysis was Popper's prime example of a theory that is immune to refutation by any possible observation. Despite the seeming inaccessibility of unconscious motivations, however, in succeeding years philosophers and psychologists pointed out that psychoanalysis is vulnerable to refutation and that Freud took account of this vulnerability. So Fancher (1973), among others, has noted that Freud modified his theories in light of disconfirming evidence, and Grünbaum has observed that many of Freud's claims about the involvement of repressed homosexuality in paranoia are eminently capable of refutation.

Grünbaum (1984) defended psychoanalysis against Popper only to offer his own alternative critique. From Freud onwards Grünbaum believes that the most important evidence in favour of the claims of psychoanalysis has come from alleged cures. For example, in 1930 the Berlin Psychoanalytic Institute issued a report on 721 analyses, 363 of which had been concluded by the time of the report. Of these, 111 patients were classified as cured, 89 as much improved, 116 as improved, and 47 as uncured (cited in Bergin and Lambert 1978). In Grünbaum's view, psychoanalysis presents a causal account of psychopathology: various symptoms are caused by repressed memories or desires; psychoanalytic treatment lifts these repressions, which removes the symptoms; hence, when patients are cured or improved, that testifies to the correctness of the causal hypotheses offered by the analyst.

The problems with treating therapeutic success as evidence for the truth of psychoanalytic claims are threefold. First, until recently, there have been no attempts to measure success rates objectively, by using observers who are unaware of the history of treatment. Second, any successes achieved must be compared with spontaneous 'cure'

rates, to show that treatment makes a difference. Finally, many different conditions obtain in therapy sessions, including support from the therapist, personal factors in treatment and, most problematically, suggestions about the causes of the patient's illness. Grünbaum argues that, since any one of these factors might be responsible for patient improvement, the inference from partial cure to the correctness of any psychoanalytic hypothesis is invalid. Of particular concern is the therapist's suggestion that the cause of the illness has now been found and hence improvement is to be expected. Grünbaum argues that the therapist's words can act as a placebo and lead to substantial improvement, simply because patients believe that they will improve.

2 Statistical and experimental evidence

In recent years, a growing number of 'outcome' studies have compared psychoanalysis with other forms of treatment, with no treatment, and with placebo conditions. Although the results are sometimes inconsistent, a review by Bergin and Lambert (1978) concludes that psychoanalysis and a number of other therapies appear to have better results than no treatment, placebos and pseudotherapies. The problem is that it is not clear what such studies prove. They appear to support the claims of psychoanalysis to therapeutic success. As Grünbaum notes, however, they simultaneously raise serious questions about the *causal claims* of psychoanalysis. For, if the basic outlines of psychoanalysis are correct, and psychopathology is a result of repressed (sexual) memories and desires, then how is it possible to account for the successes of non-analytic therapies (especially behavioural therapies), which also exceed spontaneous 'cure' rates? Since the patients have not had their repressions lifted, there should be no improvement. Other therapies might ameliorate psychological conditions without truly curing them, so the argument is not conclusive. Still, as Hume noted long ago, if apparently different causes have a common effect, it is reasonable to look for unnoticed common factors (see Causation). And Bergin and Lambert suggest that what accounts for improvement is not so much the truth of the theories underlying the different therapies, but the common placebo factors they share, such as the understanding and support of the therapist.

Comparing treatment outcomes with different therapies is an attempt to apply J.S. Mill's methods to causal hypotheses in psychotherapy. According to Mill, the way to establish that *A* (a particular treatment) is the cause of *B* (a cure) is to show that *A* reliably produces *B* in a variety of circumstances that differ in other respects and that *B* will not occur in the absence of *A* despite the presence of other circumstances (see Scientific method). Although recent studies are more sophisticated, the work just canvassed suggests what Mill fully anticipated: in complex cases, it may not be possible to disentangle all the possible causal factors and so apply his methods. Freud's defenders often object that methodological critiques of psychoanalysis suffer from exactly this flaw. Critics complain that psychoanalysis is unable to meet particular tests of scientific proof, when the real problem may be that the types of proof available are inadequate to handle the complexities encountered in psychopathology.

Similar problems have hindered attempts to find experimental evidence for or against central theories of psychoanalysis about, for example, the three phases of sexuality, the origin of the super-ego in the resolution of the Oedipal complex, or the sexual basis for the repression of unconscious ideas. Psychoanalytic claims about the causation of symptoms are complex, but only relatively simple factors can be observed or manipulated in experiments. The gap between 'experimental confirmation' and the theory to be confirmed is evident in Eysenck and Wilson's review of this literature (1973). One study was designed to test Freud's hypothesis of oral sexuality. Although the results confirmed thumb-sucking as a substitute form of oral activity, that claim is a rather bland surrogate for Freud's rich views about the oral phase of sexuality. Another study attempted to confirm Freud's claims about the Oedipal complex by looking at the proportion of male and female strangers in dreams. Again, the results were positive. More strangers in dreams were males than females and this was true to a higher degree in the dreams of males. As Eysenck and Wilson note, however, these results are compatible with many hypotheses besides Freud's very specific claim about fear of the father in response to incestuous wishes about the mother. To take an obvious example, men may dream more about men, because they are more often in the company of men; all subjects may dream more about men, because men are more salient in our society. More recent attempts to provide experimental support for psychoanalysis by using subliminal or supraliminal stimuli may well be subject to the same criticism. Establishing that there is unconscious, but active ideation in human brains is a pale substitute for Freud's rich claims about the sexual aetiology of repression (see Unconscious mental states).

3 Dream and symptom interpretation

The study just mentioned appeals only to the 'manifest' or actual, reported content of dreams. One recurring

methodological debate in psychoanalysis concerns the use of interpretations of dreams and symptoms in explaining psychopathology. Probably more than any other single issue, the question of dream and symptom interpretation reveals a huge gulf between the supporters and detractors of psychoanalysis. Dream and symptom interpretation are critical to psychoanalysis, because, along with ‘free association’, these are the primary methods by which diagnosis and remedy are possible. According to standard psychoanalytic theory, the true causes of psychopathology are hidden. They are repressed memories or desires. Hence, the analyst must find some indirect means of uncovering those causes, and dream and symptom interpretation, interpretations of particular actions or remarks, and free association are the distinctively psychoanalytic tools for accomplishing this task.

Critics have raised a host of objections. Grünbaum and others have argued that the theory that dreams are wish-fulfilments is false. Indeed, as Grünbaum observes, some of Freud’s own reports of his patients’ dreams cast serious doubts on this hypothesis. For example, a young woman dreamed that she was going on a summer holiday with her mother-in-law, something that she did not wish to do. Freud’s explanation, that she had this dream to fulfil her wish to disprove his theory of dreams as wish-fulfilments, seems to be blatantly *ad hoc*. The more standard objection to dream and symptom interpretation is that this is either an enterprise with no rules at all or with one question-begging rule: find some interpretation that relates the symptom or manifest content to a hidden sexual wish. Echoing Popper, critics object that since, given sufficient imagination, some connection to sexual wishes is always possible, the ability of therapists to make these connections has no probative value.

More recently, Fancher, Sulloway (1991) and Kitcher (1992) have argued that the theory of dreams is not an autonomous part of psychoanalysis, but follows from some of Freud’s early, but persisting views about the organization of the nervous system. If this view is correct, then it fundamentally alters the evidentiary status of the theory of dreams. Contrary to Freud’s own position and that of many of his followers, the theory would be capable of confirmation outside the clinical setting. Although it provides the theory of dreams with an alternative source of evidence, this new understanding of the place of the dream theory in psychoanalysis leads quickly to disaster. For, if the real source of support for the dream theory is Freudian neurology, then that theory should be rejected along with its outmoded neurophysiological basis.

4 The foundation in nineteenth-century science

As Quine has argued, theories can be supported both ‘from below’ (by experimental results) and ‘from above’ (by more general theoretical considerations). In considering experimental testing and therapeutic success rates - the experimental and therapeutic ‘predictions’ of psychoanalysis - we have considered only how the theory might be confirmed from below. Analysts have not tried to provide support from above for the obvious reason. Even if Freud’s views were well supported by nineteenth-century science, so much has changed that that support has long ago eroded. In fact, some analysts have taken the opposite tack and attempted to detach a ‘clinical’ part of psychoanalysis from its ‘metapsychological’ foundations, especially Freud’s claims about the flows of energy through the ‘mental apparatus’ (Klein 1976). One problem with this approach is that it makes the enterprise of psychoanalysis entirely dependent on ‘confirmation from the couch’, which is highly problematic (see §§2, 5). It also leaves psychoanalysis vulnerable to the charge that not only is it not well supported now, it never was a plausible scientific theory, but only some type of pseudoscience.

Frank Sulloway (1979) has argued that many of the basic tenets of Freud’s theory derived from important work in nineteenth-century biology. So, for example, the prominence of sexual factors in psychopathology and mental life generally would be a plausible hypothesis, given Darwin’s claims for the importance of sex in evolution. The view that psychopathology was a result of excess neural energy, or excitation, or libido - energy that was released in dreams, symptoms, jokes and slips - seems more plausible if the nervous system is understood as a reflex mechanism that seeks to rid itself of energy that has intruded into the system. Sulloway also provides great detail about the work in ‘sexology’ that preceded Freud, which was incorporated into some of the best-known claims of psychoanalysis about infantile sexuality and psychosexual development. Although Sulloway’s research deflates some claims for the originality of psychoanalysis, it provides a powerful reply to critics who dismiss the theory as wild speculation made up on the basis of a handful of not very successful case histories.

Looking back to nineteenth-century work in linguistics, anthropology and psychology also provides some grounding for methodological strategies of psychoanalysis that have been subject to withering criticisms. Several of Freud’s least popular interpretive principles were suggested by then contemporary work in linguistics. For

example, the claim that the manifest verbal content of dreams often represented the exact opposite latent content (for example, 'strength' represented 'weakness'), was consonant with Abel's hypothesis that early concepts were formed by comparison and so indicated both sides of the comparison, 'strength' and 'weakness'. The equation of the infantile with the primitive was firmly supported by anthropology and by some biologists, who maintained a 'biogenetic law' (ontogeny is the rapid recapitulation of phylogeny). Most importantly, perhaps, the method of free association itself reflects the widespread psychological assumption that different thoughts or ideas are held together by bonds of association and that it is possible to uncover these associations by asking subjects to provide lists of associates. Although much has changed in biology and the social sciences, in so far as psychology still accepts associationism, and evolutionary theory still speaks to the importance of sexual factors in human life, some parts of psychoanalysis can still receive some mild support from above (see Evolutionary theory and social science; Learning).

5 Single case histories as evidence

Although Freud offered many theoretical discussions of psychoanalysis, he often presented his ideas through the medium of the case history. Are these cases simply meant to illustrate the principles of psychoanalysis or can they be regarded as evidence in favour of one or another of its doctrines? Seemingly, case histories can provide evidence for psychoanalysis in one of two ways: a psychoanalytic claim would be confirmed either if the diagnosis produced a cure or if patients acknowledged that they did harbour the unconscious memory or desire inferred by the analyst. The problems with arguments from cures have already been noted. Patient confirmations of analysts' hypotheses are subject to some of the same difficulties, and more besides. Even more than in the case of cures, it seems that analysts' suggestions that patients have certain unconscious desires might lead patients to assume that they do have these desires, either because they wish to please the analyst or because they assume that analysts are knowledgeable in these matters. Further, a patient's confirmation of a particular unconscious desire is evidence of the analyst's correctness only if there is good reason to believe that patients, or the population as a whole, are generally reliable about the psychological states that cause their beliefs and actions. Recent work in psychology suggests that this crucial assumption may be false (see Nisbett and Wilson 1977; Introspection, psychology of).

Despite the serious difficulties with using single case histories as evidence for psychoanalysis, both Erwin (1988) and Glymour (1982) have argued that this is possible at least in theory. Erwin notes that a single case or intrasubject design can provide evidence, if the change in the patient is sufficiently dramatic. If a patient suddenly recovers from a physical illness after unsuccessful treatment by other medications, that is strong evidence of the efficacy of the new medicine. In the same way, if a patient who has been in different psychotherapies for some time with no improvement were suddenly to improve upon being offered a psychoanalytic hypothesis about the cause of the illness, that would suggest some causal connection. Although spontaneous remission cannot be ruled out, such a case would still have probative value.

Glymour has developed a very different approach to establishing the possible use of case histories as evidence. He notes that it is possible to test hypotheses in other non-experimental sciences, such as astronomy, by making inferences from observations via particular claims of the theory to further possible observations. The observations might provide evidence only when supported by other theoretical claims, but so long as these are independent of the claims to be tested, testing is still possible. This type of 'pincers' movement can be illustrated by the well-known Rat Man case. From the Rat Man's symptoms and various principles of psychoanalysis, Freud inferred that he had an unconscious wish for his father's death. But such a wish is unobservable. Given other claims of psychoanalysis, however, he inferred that this unconscious wish must have arisen from an early conflict over sexual matters. Hence he expected to find that the Rat Man had been punished for early sexual behaviour. Had this 'observation' been made, it would have offered some confirmation that the Rat Man wished for his father's death, because the evidence and assumptions supporting the inference to this wish would be independent of the evidence and assumptions that originally led Freud to infer such an unconscious wish. In opposition to Popper (see §1), Glymour notes that when Freud concluded that no episode of sexual misconduct occurred, he also recognized that his original theory was false. Although Popper might disapprove of how Freud then modified his theory, by allowing sexual fantasies as well as actual sexual encounters to be causes of psychoneuroses, from a logical point of view, the case is an example of negative evidence leading to the rejection of an early psychoanalytic hypothesis (see Scientific method).

The use of the Rat Man, the Wolf Man, and other well-known cases in presenting psychoanalysis has led Sulloway and others to investigate their accuracy. In a recent study, Sulloway argues that Freud's case histories were not particularly accurate representations of his case notes, and that in the case of the Rat Man and, especially, the Wolf Man, they exaggerated the degree to which a cure had been achieved.

6 Scientifically informed common sense

Richard Wollheim (1971), Donald Davidson (1982), Adam Morton (1982) and others suggest a different way of regarding Freud's theories, which provides a different source of possible evidence. On their view, psychoanalytic hypotheses about the causation of behaviour are of a piece with ordinary, common-sense explanations of behaviour (see Folk psychology). The standard view of 'common-sense' psychology, which dates back at least to Hume, is that actions are caused by the agent's beliefs and desires. Although this has sometimes been debated, the general view today is that, in discovering the beliefs and desires that led to a particular action, we are discovering both the cause of the action and the reasons for which it was done (see Reasons and causes). It is the latter feature that is distinctive of psychological explanation, for it permits actions to be understood in terms of their rational justification (see Explanation).

According to these philosophers, the best way to understand psychoanalysis is by seeing it as extending common-sense psychological explanation to the realm of psychopathology or the irrational. At first, this seems paradoxical, because it suggests that Freud and his followers are trying to provide rational explanations of the apparently irrational. Although this is true, it becomes more plausible if we consider exactly why certain actions are regarded by psychoanalysis as pathological. According to psychoanalysis, pathology results when the cause or causes of actions or dreams are unconscious wishes or desires. If a wish is unconscious, then it is beyond the realm of rational control. Since the unconscious tolerates contradictions, no presumptively relevant evidence about the inappropriateness of a wish can be brought to bear on it (see Unconscious mental states). So, if a young man's belief that his father despises him is unconscious, then it cannot be undermined by words or gestures indicating quite a different attitude on the part of the father. Even though the belief is irrational in this sense, however, it can still rationalize the man's behaviour by explaining why he takes certain defensive measures to ward off possible aggression from his father. Hence, although unconscious wishes and desires are irrational in the sense that they cannot be touched by reasons, they are rational in that they can provide reasons for action. If this is the correct understanding of psychoanalytic explanation, as an extension of common-sense psychological explanation, then it can be argued that the basic approach of psychoanalysis is supported by the continuing successes of common-sense psychology. Common-sense psychology can provide no support for any particular psychoanalytic claims, such as the homosexual aetiology of paranoia, but it can lend credence to the general enterprise of looking for conscious or unconscious beliefs and desires that will make the agent's actions comprehensible in terms of reasons. Conversely, psychoanalysis can make common sense more scientific, by delineating the true scope of rational explanation.

Supporting psychoanalysis by appeal to common-sense psychology is highly controversial, for several reasons. At one extreme, some philosophers will deny that common-sense psychology can provide useful support, because it is itself an unscientific attempt to understand human behaviour. In particular, critics note that it is far from clear exactly what counts as an adequate rational justification of an action (see Rationality, practical). Even those willing to allow the acceptability of common-sense psychological explanations in straightforward cases would object that complex cases, especially those involving pathology, are too tangled to permit any degree of confidence in a particular belief-desire explanation. Finally, assimilating psychoanalytic hypotheses to common-sense psychological explanations is possible only if the latent content of dreams, slips, actions and so forth can be fathomed by the interpretive methods of psychoanalysis and, as we have seen, many critics find these methods objectionable.

Psychoanalysis, post-Freudian

The basic concepts of psychoanalysis are due to Sigmund Freud. After establishing psychoanalysis Freud worked in Vienna until he and other analysts fled the Nazi occupation. Post-Freudian psychoanalysis has evolved in distinct ways in different countries, often in response to influential analysts who settled there.

Freud's patients were mainly adults who suffered from neurotic rather than psychotic disturbances. He found their psychological difficulties to be rooted in conflict between love and hate, caused by very disparate, often fantastic, images deriving from the same parental figure. These images provided the basic representations of the self and others, formed by processes of projection (representing the other via images from the self) and introjection (representing the self via images from the other). The internalized image of a parent could be used to represent the self as related to some version of the other, as in the formation of the punitive super-ego, or as like the other, as in the identification with the parent of the same sex through which the Oedipus complex was dissolved.

Later analysts, including Anna Freud and Melanie Klein, observed that the uninhibited play of children could be seen to express fantasies involving such images, often with striking clarity. This made it possible to analyse children, and to see that their representations of the self were regularly coordinated with fantastic representations of others, with both organized into systematically interacting systems of good and bad. Emotional disturbance was marked by a fantasy world in which the self and idealized good figures engaged in conflict with hateful bad objects, unmitigated by any sense that all derived from the same self and parental figures.

Such observations made it possible to confirm, revise and extend Freud's theories. Klein saw that symptoms, character and personality could be understood in terms of relations to internalized fantasy-figures, laid down in early childhood; and this extended to psychotic disturbances, such as schizophrenia and manic-depressive illness, which turned on the particular nature of the figures involved. This gave rise to the British object-relations approach to psychoanalysis. It also influenced the development of ego-psychology and self-psychology by Hartmann, Kohut and others in the United States, and Lacan's attempt to relate psychoanalysis to language, in France.

1 Melanie Klein, object-relations and the British school

The first, major post-Freudian innovations, and the most controversial, stemmed from the work of Melanie Klein. Klein realized that psychic structure and function could be understood in terms of relations to fantastic unconscious figures, which she called 'internal objects', and focused psychoanalytic investigation on them. For example, a little girl who suffered obsessional symptoms as well as depression played at being a queen who was getting married. When she

> had celebrated her marriage to the king, she lay down on the sofa and wanted me, as the king, to lie down beside her. As I refused to do this, I had to sit on a little chair by her side, and knock at the sofa with my fist. This she called 'churning'…immediately after this she announced that a child was creeping out of her, and she represented the scene in a quite realistic way, writhing about and groaning. Her imaginary child then had to share its parents' bedroom and had to be a spectator of sexual intercourse between them. If it interrupted, it was beaten…. If she, as the mother, put the child to bed, it was only in order to get rid of it and to be able to be united with the father all the sooner.
>
> (1975, vol. 2: 40)

Freud had noted that the parents are frequently symbolized in adult dreams by the figures of king and queen. The play described above could be seen to use the same symbolism, and so to represent the child's unconscious fantasies about her parents (whom in real life she treated with excessive but demanding fondness). Here the child's representation of adult sexuality is partly symbolic (for example, in terms of 'churning' or something knocking something); but the referent of the symbolism can none the less be inferred from the context (the activity takes place after the wedding, with the parents lying together in bed, and is followed by the birth of a child).

The fantasies expressed in this game were repeated in many others, and in many related psychological constellations. Hence it was possible to understand the little girl's obsessions and depression by reference to what she felt to be happening between herself and the fantastic unconscious versions of her parents represented in her

play (see Unconscious mental states).

How was it possible to understand the establishment of the fantastic *bad* internal objects central to conflict and psychopathology? Klein found *envy* to be particularly important in this process. This can be acute in children and infants, since they are particularly small, helpless and dependent. According to Klein, little children therefore seek relief from envy, as well as other emotions felt as bad, by both projection and introjection. In the former they try to locate in others whatever is felt as bad in the self, including envy and other forms of aggression; and in the latter to locate in themselves whatever is felt as good in others. This produces both *splitting of the self* and *splitting of the object*, in which the former is represented as good but lacking aggression, and the latter as bad and lacking goodness, both unrealistically.

These processes explained the structural features of children's fantasies, in which 'good' figures, identified with the self and sharing its goals, are systematically menaced by 'bad' figures which oppose them. Despite being kept out of consciousness, or represented as distant or alien, the 'bad' figures threaten to confront the self, or impinge upon or invade it, with mirroring directness. This is because such figures contain split-off aspects of the self, and so relate to those from which they are split with uncanny precision. Thus the little girl above dealt with aggressive envy of her parents' sexuality by such projection, and so unconsciously represented them as having sexual relations to make her envious. Hence she felt herself powerless and surrounded by bad figures, and so sought to imagine herself in an idealized way, as a rich, powerful and enviable queen.

Since such projection creates images of the other unconsciously identified with disowned aspects of the self, Klein called it 'projective identification'. (Anna Freud described a comparable mechanism as 'identification with the aggressor'; Klein's description applies where the image of the aggressor is itself formed by projection.) This mechanism could be seen as basic to both individual and social thinking, ordering human relations on primitive patterns of idealized 'us' versus bad 'them'.

Klein also proposed far-reaching hypotheses about infancy. She held that object-relations had an innate basis, and began almost from birth. Thus the infant related to the mother and to parts of her, especially her breast, before coming to understand her as a single enduring object. The disparate images of 'good' and 'bad' objects shown in analysis were laid down before the infant formed an integrated conception of the human body, or realized that the parental figures it felt as very bad or very good were in fact the same (see Cognition, infant; Cognitive development; Nativism).

In the first three or four months of life, Klein hypothesized, the infant made sense of its experience by building up concepts of episodic objects, which were anatomically incomplete, modelled on various parts of the body, and liable to be extremely good or bad, depending on the nature of the experience in which they were involved. During the fourth month, however, the infant began to unify its conception of the mother, and so to regard her as a single person, who was anatomically whole, complete and enduring.

Recent experiments seem partly to illustrate these ideas. For example, Campos observed that a 4-month-old infant made angry by someone's taking something away will direct expressions of anger towards the depriving hand, whereas by 7 months the infant will direct anger at the offending agent's face (see Campos *et al.* 1983). Bower (1982) used mirrors to display to infants three simultaneous images of the mother. Infants of 3 or 4 months are undisturbed by the apparent presence of three 'mothers', and interact with them in turn, preferring each to (images of) women not their mothers. Past 5 months, however, the sight of three 'mothers' becomes intensely disturbing. It seems that the infant does not specifically prefer enduring singularity to episodic multiplicity until this time.

Klein thought that the formation of the image of the mother as psychologically and physically unified was of particular importance. She called the pre-objective phase of life the 'paranoid-schizoid position', the term 'paranoid' indicating the extremity of the baby's potential for anxiety, and 'schizoid' the fragmentary way it represents itself and its objects. In acknowledging the mother as a single enduring object, the infant must begin to endow her with complex and apparently contradictory characteristics shown over a variety of episodes. In particular, it must recognize that she is the frustrating object towards which it feels anger and hatred, as well as the gratifying object towards which it feels love. This more complex object must now also be seen as distinct from the self, capable of absence, unique and irreplaceable. (This may explain why infants who have not before protested at their mother's leaving may at 6 or 7 months develop intense anxiety at separation; according to Klein, the infant is

then consolidating the realization that the mother leaving is the only mother it has.)

In response to these changes the infant begins to dread the loss of the object, and becomes concerned to care for it, protect it and repair the harm inflicted on it in fantasy. This Klein called the ‘depressive position’, so named because unification entails liability to depression about damaging the object (principally the feeding, caring mother). The dialectic of projection and introjection correlates these more realistic and complex attitudes to the object with complementary changes in the self. This unification constitutes the emotional aspect of the establishing of the reality principle (see Freud, S. §7), and so coincides with a diminution in the role of wish-fulfilling fantasy, splitting and projection.

According to Klein a range of psychic disturbances can be understood in terms of failure to achieve this Kantian synthesis. The worst case is schizophrenic illness, in which the infant is liable to particularly violent splitting and projection, and so cannot, in Hume’s phrase, ‘unite the broken appearances’ of self and other (see Hume, D; Mind, bundle theory of). At deep levels the object remains represented as a multiplicity of episodic presences housing projected aspects of the self, which is therefore radically fragmented, depleted and threatened by persecution. In the less severe cases of manic and depressive illness, the object consists of partly integrated bad (hated) and good (idealized) parts. In mania the subject fantasizes triumphing over the bad and possessing the good of such an object, and in depression destroying the good together with the bad.

Klein’s ideas were extended by Bion (1961) to groups and by Segal (1990) and Bion (1989) to the infantile origins of symbolism and thought. Many analysts, however, have tended to accept and extend Klein’s descriptions of relations to real and fantasized objects, while disagreeing with her hypotheses about infancy. Winnicott (1958) formulated further striking conceptions, such as the ‘transitional object’ and the ‘true’ and ‘false’ self, and Fairbairn (1954) attempted a full-scale restatement of psychoanalysis in terms of object-relations. Such accounts have now been elaborated by all schools, including that of ego-psychology (see Kernberg 1995). An ethological account of early object-relations by Bowlby (1969, 1973) fostered extensive empirical study of attachment (Ainsworth 1985).

2 Ego- and self-psychology in the United States

Freud introduced the ego and the super-ego as functional systems mediating between the individual’s innate instinctual drives and the external world. This theory was elaborated by Anna Freud (1936) and developed more systematically by Heinz Hartmann and his colleagues in the United States.

Hartmann (1939) distinguished clearly between a person’s conscious and unconscious representations of the self, and the ego as a system whose working could be described in impersonal terms. This system developed out of an ‘undifferentiated matrix’ present at birth and prior to both ego and id, and could be seen as having the general function of *adaptation*, that is, of relating the organism to the physical and social environment. Hence study of the ego could form a bridge between biology and the social sciences, rendering psychoanalysis a more general psychology.

Hartmann held that a main achievement of the ego was the attainment of*autonomy*, that is, the capacity to function with a degree of independence and self-sufficiency; and he linked this with normally conflict-free functions such as locomotion, which had received little attention in psychoanalytic theory. He related autonomy in object-relations to ‘object constancy’, the ability to represent self and other consistently, despite absence and changes in emotion (see Cognition, infant).

This notion was carried into empirical research by Renée Spitz (1965), who made a number of pioneering efforts to study ego-development in infancy, including film studies of infants and mothers, focusing on smiling, anxiety at separation or encountering strangers, grief at loss of contact, and the like. Spitz thought that the development of object-relations could be detected in a number of features of overt infantile behaviour: the way the infant related the mother’s breast and face, subsequently following her face with its eyes; the smiling response, followed by social smiling, which he took to indicate the inception of social relations; the onset of 6- to 8-month ‘stranger anxiety’, which indicated recognition of the mother as a specific individual; and the capacity to gesture (or verbalize) ‘No!’, which he took to show both identification with the mother as one who refuses, and a distinctive form of communication.

More detailed hypotheses about the development of the ego and object constancy were set out in work by Edith Jackobson (1964) and by Margaret Mahler (1968) and her associates. Mahler held with Spitz that in early life the mother serves as an 'external ego' for the infant; she argued that the infant first experiences the mother in a phase of *symbiosis*, during which it feels itself blissfully to merge with her, and imagines the two as a 'dual unity' with a common boundary, or what Jackobson called a 'self-object'. As the infant forms a more distinct image of the mother it develops a sense of basic trust, conveyed in smiling and eye contact; then, beginning to distinguish more clearly between itself and the mother, it enters the phase of 'separation-individuation', not completed until the third year. In this phase the infant builds up representations of 'good' and 'bad' self and objects, and finally unifies these into more stable and realistic representations, in which the characteristics of the self are fully distinguished from those of its objects.

Mahler divided this process into three sub-phases, marked by discernible patterns of infantile behaviour. The first is that of *differentiation*, lasting (roughly) from 5 to 9 months, during which the infant 'hatches' from the dual unity and focuses perception and action on the world. This is followed by a period of *practising*, in which the infant increasingly turns away from the mother to explore the environment, first by crawling and then by walking. As the child's enjoyment of its own capacities conflicts with its increasingly realistic sense of dependence on the mother there follows a phase of *rapprochement*, during which the child seeks to reconcile desires to remain in union with the mother with desires to become a separate and autonomous individual.

This conflict can show in a number of ways: new anxieties about separation; alternating 'shadowing' the mother, allowing no separation, and darting away, requiring her to prevent it; ignoring the mother's presence or departure, to deny her importance; 'becoming' the mother in her absence, and so creating a pseudo-independent false self; attempting to control or coerce the mother, to deny her autonomy; and so forth. In the ensuing 'rapprochement crisis' the child feels both longing and anger towards the absent mother, but directs the longing to an idealized 'good mother', while projecting the image of the 'bad mother' onto some resented substitute. The resolution of this phase, similar in structure and outcome to Klein's depressive position, is marked by diminution in splitting of this kind, so that the child approaches object constancy (see Cognitive development).

Much of the clinical work of ego-psychologists was concerned with feelings about the self linked to failures in individuation and autonomy. This set the stage for Heinz Kohut (1977) to argue that the development of a new psychoanalytic theory, 'self-psychology', was required to explain the pathology of the 'fragmented' and 'depleted' self. In attempting to frame such a theory Kohut re-employed Jackobson's term 'self-object', to designate another who is *experienced* as performing a psychological function essential to the self, and so as part of the self. This restored the phenomenological aspect of Freud's notion of an ego partly constituted by relations to its objects, lost in Hartmann's disambiguation.

In early life the primary self-objects are the parents - for example, the mother in her role as 'eternal ego' to the infant - and later versions inherit their significance from these. The 'primary psychological configuration' for self-psychology is thus the experience of the relation between the self and the self-object, and in particular that of the 'empathy', or degree of attuned adequacy, with which the self-object responds to the needs of the self. When the self-object responds appropriately to expressions of need, the infant's anxiety is replaced by an experience of merging with a powerful and calming self-object, whose functions, given repeated experience, can ultimately be internalized.

Kohut argued that two basic self-object functions show themselves in particular forms of transference to the analyst. There is an 'idealizing transference', in which the analyst is represented as embodying the kind of perfection with which the patient wishes to merge; and a 'mirror transference' in which the analyst is represented as having the function of responding empathically to the patient's narcissistic and grandiose displays, so as to sustain the patient's self-assertion through approval, mirroring and echoing. These transferences are best explained on the hypothesis that it is especially important for the infant's primary self-objects to provide both empathic mirroring for the infant's self-assertive, exhibitionistic and grandiose self, and embodiments of idealizable functioning with whom the infant can feel it merges. If these requirements are met, then the infant's grandiose self-assertions can develop towards realistic ambitions and goals, and its notions of ideal perfection towards realistic ideals and values.

Since the cohesion of the self depends upon these functions, the child (or the analytic patient in whom such

infantile needs are re-activated) responds to the parent's (or analyst's) failures in performing them with an overwhelming hatred and desire to hurt, which Kohut calls 'narcissistic rage'. The infant seeks total control over the self-object's responses, which it cannot achieve. If it remains without adequate empathic mirroring or opportunity for idealization and merging, it may become convinced that the environment is hostile, a situation Kohut compares to Klein's paranoid-schizoid position.

3 Psychoanalysis and language in France

A main tenet of all psychoanalytic approaches is that desires from infancy are constantly re-symbolized, so as to secure representational pacification throughout life. Analysis seeks to trace the constantly evolving modes of representation of the self and the objects of its desires; and this is done through language, a particular form of symbolic representation. In seminars from 1953 to the 1970s, Jacques Lacan attempted a re-presentation of Freudian theory centred on symbolism and the relation of psychoanalysis to language.

A main theme in Lacan's work, like that of Klein and Kohut, is a lack of unity in the self, which Lacan takes as an ineliminable consequence of the processes that provide representation for the self and the objects of desire (see Alterity and identity, postmodern theories of §2). As a first example, he considers the infant's recognition of its own image in a mirror. The infant joyfully assumes this external image, which represents it as possessing a wholeness, permanence and unity which it feels itself to lack, and which anticipates and facilitates its ability to move and relate to others. Paradoxically, however, this enabling identification is also an alienation; for the infant identifies itself with something it feels itself *not actually to be* and which it *may yet fail to become*. Identifications with others are alienating in the same way, so that the self is constituted by images that threaten to confront it as reminders of its own lack of being. The subject is thus formed in a potentially rivalrous and aggressive relation with its own self, and thence with others.

Lacan describes these alienating self-images, as well as others created in projection, introjection and fantasy generally, as constituting an order of representations which he terms 'the imaginary'. This he contrasts with the 'symbolic order', which encompasses the personal and social systems of signs whose elements are intrinsically constrained by rules of combination and substitution like those of natural language (see Syntax). Freud's discussions of dreams and symptoms, he argues, shows them to be constructed in accordance with such rules; so, the combinations and substitutions of (representations of) objects in dreams and symptoms, or again in the course of development, can be seen as instances of metaphor, metonymy and other linguistic forms. The unconscious is thus structured like a language, and representations of the subject and objects of desire are products of symbolic substitution, and shaped to fit the elements and rules of the combinatory systems through which they are articulated and satisfied.

This account extends to society, for Lacan regards structures of kinship and social exchange as further symbolic systems. In particular, the prohibition of incest, characteristic of all human societies, can be seen as a law regulating the relations (combinations) of men and women, taken as elements partly constituted by their role in exchanges among groups which compose society. Thus, according to Lacan, the resolution of the Oedipus complex is a development in which the boy forgoes an imaginary relation with the mother to occupy a place in a larger order, which is symbolic, social and constitutive of human culture. As in the prior instance of the mirror, the child secures a potentially fulfilling identity via the enabling but alienating assumption of an image - in this case that of the symbolic father, who embodies the social laws which regulate sexual desire and provide for its procreative satisfaction.

4 Comparisons

The diversity of psychoanalytic theories may conceal their underlying convergence. For example, Lacanian criticisms of ego-psychology assume a common basic account of the formation of the self, and an interest in symbol-formation is common to all schools. Again, Lacan's mirror stage illustrates a particular aspect of Klein's depressive position - namely, identification with something felt to be whole because seen as having spatial unity and permanence, and enviable on that account.

The main disagreements among the other approaches sketched above concern the first year of life. Klein hypothesized that envious projective identification was active from early infancy, whereas Kohut and the

ego-psychologists regarded symbiotic unity as prior to envy and aggression, ego-weakening splitting and fantasies of relating to good and bad objects generally. Studies of infant cognition, imitation and communication (see Stern 1985; Mehler and Dupoux 1994) suggest that even very young babies might engage in psychological exchanges comparable to projective identification, which can also be seen as the establishing of object- and self-object relations (see Cognition, infant; Mind, child's theory of). In addition, empirical studies of attachment suggest that patterns of object-relations formed in infancy can be traced throughout life, and from one generation to the next (see Bretherton and Waters 1985; Cichetti and Cummings 1990). Some of these patterns coincide with psychoanalytic accounts, and recent work in the United States (Kumin 1996) relates them to both Klein and Kohut. Whether a conceptual and empirical synthesis along these lines will prove successful remains to be seen.

Psychology, theories of

The object of study in psychology is the experience and behaviour of organisms, particularly human organisms. Psychology resembles the other sciences in employing methods appropriate to material phenomena but, unlike them, the mind (sometimes held to be immaterial) is among its objects of study. If the mind were immaterial it is difficult to see how psychology could proceed. Psychology differs from the other sciences in that understanding may not permit prediction and/or control of the phenomena. This is a consequence of the fact that human organisms may become aware of causal factors that would otherwise have determined their experience or behaviour. Being aware, they have a choice. (This is not, of course, to deny that the choice may itself be determined by more remote factors.)

In the seventeenth century, Descartes proposed that the mind (or soul), though immaterial, was nevertheless capable of two-way causal interaction with the material body. It is often held that what is immaterial cannot interact with what is material but Descartes' proposal was, in its context, so valuable that it has ever since exercised a profound influence on philosophy and on what most of us take for granted (for example, the unexamined belief that the mind/soul is, in some sense, immaterial but does, in some sense, interact with the body).

The possibility of scientific psychology was preserved by Leibniz's hypothesis of psycho-physical parallelism (according to which the deity keeps mind and body running in parallel, though there is no causal interaction between them). This view did not survive the passing of an era of universal (and largely unquestioned) religious belief. At the beginning of the twentieth century behaviourism tried to do without mind, it also tried to avoid surreptitious appeal to the lay person's unexamined 'mind' concept. In the 1960s, the cognitive revolution in psychology substantially broadened the range of phenomena under investigation but at the cost of allowing appeals to an unexamined 'mind of last resort'.

The headlong advance of the computer, which has taken over many functions previously reserved to members of the human species, leaves open the question whether it will, one day, take over all of them - or will be permitted to do so.

1 Origins

The belief is deep-seated that human persons are, by virtue of possessing conscious minds, beings of a different order from the bodies with which they are associated - which share material reality with the other physical objects in our universe. The belief is not unreasonable since each of us can validate it, so we think, from immediate experience. Until the seventeenth century it was generally agreed that the 'mind/soul' constituting the person was a substance resembling the body but with the matter taken out. Christian dogma held that, on judgment day, all souls would resume existence as physical bodies. In the seventeenth century, Descartes first proposed the more etiolated conception now current. The mind/soul remains immaterial (thus suffering none of the disabilities attached to material existence) but is no longer supposed to have the external form of the body. It is, however, still capable of two-way, causal interaction with the body. Descartes' proposal was, historically, of very great significance since it proved acceptable to the Church and allowed a distinction to be drawn between knowledge related to the soul (the prerogative of the Church) and knowledge related to the body (including the human body) which could freely be advanced by scientific investigation. Prior to Descartes no such distinction had been drawn and a scientist might be guilty of heresy for holding opinions that appear to us to have no religious content at all (for example, Galileo and the moons of Jupiter).

Descartes was aware of the physical existence and functions of the sense organs but, in his view, their purpose was to model objects in the real world for presentation to the mind/soul via the pineal gland. Collins (1973) draws attention to this radical change of emphasis. The old philosophy held, with Descartes, that objects in the real world cause changes in the perceiving organism. But what was perceived (according to the old philosophy) were objects in the real world. What was perceived according to Descartes were models of the objects, formed by the sensory systems of the perceiver. Descartes' substitution is rational for an avowed mind/body dualist but ceases to be rational if there is no postulated 'mind' to which the models may be presented. Why do we need models if we have the real things in our perceptual field? Surely all we need is information about the real things, enabling us to respond appropriately to them? The majority of contemporary theorists follow Descartes in rejecting this argument

(for example, Marr 1982). They seek only to specify how the organism constructs its hypothetical internal models. Gibson (1979) is the exception; insisting that what we perceive are objects in the real world, not models of them (see Dualism; Perception §1).

2 The emergence of psychology

Psychology was the last of the established sciences to break free from philosophy (the word 'psychology' is rarely used prior to the nineteenth century). But the change of emphasis to which Collins (1973) drew attention had profound effects on philosophy which have in turn influenced psychology. If Descartes' substitution is accepted, it becomes possible (perhaps obligatory) to adopt what Collins calls the 'egocentric, sceptical perspective' - to doubt the existence of the external world and even the continuity of the perceiving person. The models may, after all, have no material correlate; they may exist only in the immaterial mind that perceives them. Philosophers since Descartes have laboured mightily to prove the postulations of everyday thinking - that we exist and that a real world external to us exists - but without success.

Psychology cannot allow the possibility that an immaterial 'mind' that is not law-governed interacts causally with each material human body; the intervention of such a mind would put the body's behaviour beyond the reach of science; the behaviour would still be observable but no longer predictable, even in principle. At first, Leibniz's doctrine of pre-established harmony appeared to offer a way out of the dilemma, in the form of 'psycho-physical parallelism'. In a world in which dogmas of the Church were widely accepted it seemed legitimate to postulate that mind and body might not interact but might, by God's grace, run in parallel - like two ideal clocks, started at the same moment, that always show the same time though there is no connection between them. Psycho-physical parallelism was tacitly accepted during the greater part of the nineteenth century. It was compatible with the theories of memory and thinking then taken for granted according to which ideas/mental images could become associated by contiguity of time and place in individual experience, or as (apparent) cause and effect. The occurrence of one would then be likely to elicit others with which it had been associated in the past. A 'mind' was tacitly assumed to be available to draw appropriate inferences from the associations furnished by experience. At about the same time, mathematics moved on from concern with the development of new, useful mathematical techniques to worries (often associated with the problem of infinitesimals) about the validity of the techniques. They appeared to work, but could they be relied upon?

At the end of the nineteenth century the theoretical status of psychology was uncertain. There had been advances in neurophysiology sufficient to show that the brain was intimately involved in behaviour and one or two lone voices had been heard advocating a purely physiological psychology. Generally, however, physiologists were careful to keep their options open. Fritsch and Hitzig (1870: 96), for example, believed that 'some psychological functions and perhaps all of them, in order to enter matter or originate from it need certain circumscript centers of the cortex'. Wilhelm Wundt opened the first psychological laboratory at Leipzig in 1879 but he held strong views on what might and might not be done in the laboratory. Basic sensory functions were investigated to establish what was the least perceptible stimulus, or the least perceptible difference between stimuli, using controlled introspections in which the subject reported verbally whether the stimulus was present or whether two stimuli differed (Wundt 1894). Wundt did not, however, regard the higher mental functions as suitable topics for the laboratory, they might only be studied by historical and/or descriptive methods. He insisted on the mind/body distinction and succeeded (1907) in aborting a programme of laboratory investigation into higher mental functions begun in Würzburg a few years earlier (Humphrey 1951); not, however, before it had been established that many such functions proceed in the absence of introspectible mental content. This finding was important as a refutation of one central argument of associationism which maintained that associated ideas/images must necessarily be in consciousness, that is, they must be introspectible. Titchener studied in Wundt's laboratory but, on his return to the USA, he too conducted introspective investigations into 'higher mental functions'. He maintained that failure to find introspectible mental content showed only that the subject had not tried hard enough and once confessed himself 'not at all astonished to observe that the recognition of a (shade of) gray might consist of a quiver of the stomach' (1909: 179).

3 The establishment of a scientific psychology

At the beginning of the twentieth century, psychology was still obsessively concerned with the problem of consciousness. Animal psychology asked only whether or how far animals could be said to possess consciousness.

But philosophical thinking on the subject had moved on. It is a relatively short step from psycho-physical parallelism (where the hand of the deity keeps mind and body on parallel courses) to epiphenomenalism where mind and body keep on parallel courses because mind has no independent causal status and simply reflects what is going on in body (see Epiphenomenalism). Either way psychologists may legitimately proceed to the experimental investigation of behaviour but the latter view sheds surplus theological baggage that had become progressively less easy to accept. Consciousness does not need to be denied to man or animal and may continue to be employed as a means of access (via language) to human subjects. However, no separate account need be given of the functions of consciousness since it has none.

J.B. Watson, the founder of behaviourism, was a philosopher who had become interested in animal behaviour (see Behaviourism, methodological and scientific). Watson (1913) asserts that consciousness should rightfully play no greater role in psychology than it plays in chemistry or physics. He appears to mean that it should play only the role allotted to it in associationism, as an arena in which observed associations may be interpreted as evidence of the existence of laws governing the observed phenomena (for example, of physics or chemistry). This should not be an acceptable view in psychology, since the psychologist includes in his remit the mind which does the interpreting, though it does well enough in the other sciences. Watson later advocated the study of observable behaviour only, without any reference to internal, unobservable ‘minds’. (A point of view maintained even more strongly by B.F. Skinner (for example, 1974).) Neither behaviourism nor associationism offers any satisfactory account of how or where theories (of which behaviourism and associationism are themselves examples) are constructed.

Watson believed at this time that ‘thoughts’ might be nothing more than sub-threshold movements of the speech organs and tried in his laboratory to obtain photographic records of such movements. Koch (1964) reports Lashley as having told him that Watson hoped to present the photographic evidence in his presidential address to the American Psychological Association (1915) but being unable to obtain any, adopted the work of his student, Lashley, on conditioning (with due acknowledgement). Thus was born the association between behaviourism and conditioning theory which occupied most US academic psychologists for the next half century. Lashley had encountered Pavlovian theory in Germany (Pavlov’s work had been translated into German although no English translation appeared until 1927). Watson (and, subsequently, Clark L. Hull) developed Pavlov’s theory into ‘learning theory’. Something was lost in the transition, since the US theory was frankly mechanist whilst Russian theory, though materialist, was never mechanist. (Mechanism was politically unacceptable in the USSR; account had to be taken of consciousness since both Marx and Lenin had used the term.) US theorists avoided reference to ‘mind’ or ‘consciousness’ since the intellectual tradition to which they subscribed equated consciousness with mind and mind with inaccessibility in principle to scientific investigation. The fundamental unit of behaviour was, for them, the link between stimulus and observable response (the S-R bond). Hull (1930; 1935) tried to show how higher mental functions might be explained as sets or sequences of these fundamental units but the basic theoretical and experimental task was, in his view, to understand the unit. Hull and his followers are said to have obtained almost total hegemony over US academic departments of psychology in the period 1920-1950 but the hegemony did not survive Hull’s death in 1952. (US behaviourism is critically evaluated in Rozeboom (1970); for Russian work over the same period see Payne (1968) and Razran (1971).)

4 The contemporary orthodoxy

The demise of behaviourism and its replacement by cognitive, ‘information-processing’ psychology in the so-called cognitive revolution of the 1960s, was motivated primarily by a desire among experimental psychologists to work on more interesting topics than Hull had permitted. But it must also be remembered that a generation of psychologists who possessed a degree of philosophical sophistication was dying off. The new generation had often studied nothing but psychology. Until the 1960s, most psychologists had recognized the desirability of a central, theoretical framework, performing the function in psychology that atomic theory performs in physics and the theory of complex molecules, in biology. They had also recognized the undesirability of referring unresolved issues upwards to an unspecified, higher supervisory level; that is, in effect, to the operations of a (possibly immaterial) mind. Since the 1960s neither of these restrictions have been observed. There has been an exponential increase in the range of topics investigated and the sophistication of the techniques employed but few significant advances in our understanding of psychological issues.

Sutherland (1979) despaired of experimental psychology using human or animal subjects since there are simply too many possible contaminating factors to allow rational interpretation of the results obtained. He recommended that efforts should be devoted either to cognitive science (that is, the computer simulation of behaviour) or to neuroscience (the micro- or macro-physiology of the brain). There has been no significant reduction in the flow of experimental papers but both cognitive science and neuroscience have succeeded in establishing themselves as independent disciplines. Cognitive science takes symbols for granted and has tried to develop ways of manipulating them by computer that approximate to various human mental functions. Recently, technological advance has brought in the possibility of 'connectionism' (Rumelhart and McLelland 1986), which has the advantage of employing analytic methods resembling those of the brain more closely than do the methods of symbolic computing. Proponents of symbol processing (or 'artificial intelligence') and of connectionism, often profess to see their respective disciplines as incompatible alternatives but since the latter appears to model symbol formation and the former takes symbols for granted, it is likely that an accommodation will be reached. It remains to be seen whether this will contribute substantially to our understanding of human psychological function (see Artificial intelligence).

At the beginning it was suggested that human beings had, by the seventeenth century, evolved a monistic conception of human nature, in a direct perceptual relationship with the natural world outside itself, that was fundamentally sound. Unfortunately this conception had, over the centuries, acquired encumbrances relating to many tangential issues of religion and metaphysics that rendered the whole a positive block to further progress in human knowledge. In the seventeenth century the block was broken; physical and biological scientists were then free to proceed unencumbered - whether the mind was material or immaterial was of no consequence. For the psychological scientist this is not, of course, the case. If mind is immaterial then psychology has, as we have seen, no obvious way to proceed. The response of many psychologists has been to insist that the mind is, of course, material but to act as if there existed nevertheless an immaterial 'mind of last resort' that perceives and manipulates the models supposed by cognitive psychologists (following Descartes) to comprise the furniture of the mind. The activities of this 'mind of last resort' should constitute a significant part of the subject matter of psychology but are often passed over.

5 Marginal influences

The Gestalt movement (Koffka 1935) was a legitimate reaction against the late nineteenth-century view that a theory of perception could be derived from data on subjects' responses to punctate stimuli - points of light or brief pure tones. The Gestaltists' fundamental observation (the 'phi' phenomenon) was that if two adjacent points of light are flashed in quick succession, what the subject sees is one point of light moving from the first location to the second. The experience is unequivocal and many related phenomena have been discovered. The Gestalt emphasis on perceptual holism was salutary but they have advanced no viable alternative theory of perception (see Gestalt psychology).

The experimental work of Jean Piaget on human developmental psychology was influential in the UK and in the USA but his theory was not. He devoted a long life to the elaboration of a biologically-based theory of human development which may yet prove to be significant (Gruber and Vonèche 1977).

Phenomenological psychology, stemming from Brentano (§2) and Husserl (Thinès 1977), has sometimes limited itself to detailed analysis of subjects' states of consciousness but more recently (for example, Harré and Gillett 1994) emphasis has been placed on discourse between persons and on the social construction of personality. There is, some believe, no necessary conflict between a structural psychology that sets out to achieve scientific understanding of the human organism - the evolved 'thing' that is capable of doing what we know human beings have done and can do - and a discursive psychology concerned only with what the organism does in its interaction with other organisms, but both have necessarily to confront the question of logic. There is something inherently odd about founding logic, as at present, outside psychology - though logicians are unanimous in rejecting what they call 'psychologism'. It may be worth noting that Husserl (who is often cited as the final authority for the rejection of psychologism) thought his views on that subject had been grossly misrepresented. Husserl (1929) makes it clear that he thought he had shown only that logic could not be founded in an associationist psychology of mental contents. He believed that it could and must be founded in a cognitive, structural psychology (see Phenomenology, epistemic issues in).

6 Theories of personality

So far, this entry has been concerned with theories that try to answer the question 'what sort of thing is the human organism and how should it be studied scientifically?' As we have seen, another level of theorizing considers the person in interpersonal interaction, in the development of 'personality'. Such theorizing frequently starts out from the malfunctioning or neurotic personality, a theory of normal personality may or may not emerge. Sigmund Freud remains the outstanding theorist at this level. He constructed a theory of normal human development with an associated therapeutic method to correct developmental anomalies. The former was the more important in his view; he never had much confidence that the latter would do more than alleviate a patient's worst difficulties. By 1914 he had already acquired a number of US disciples with whom he lost contact during the First World War. They were largely responsible for the growth of psychoanalysis as a medical speciality, offering to cure neuroses as the orthopaedic surgeon cures broken limbs. Freud regarded neurosis as the inescapable accompaniment of civilized living - since the latter is entirely unnatural to man. Both are consequences of the diversion of libidinal energy whose natural object is physical survival and reproductive success. By complex evolutionary processes man has civilized himself, using energy surplus to what was required for survival or could be dissipated in the struggle for reproductive success (since civilization usually demands at least the pretence of monogamy). Energy not dissipated in sexual activity or sublimated in the achievement of economic, artistic or other non-sexual goals, must inevitably issue in neurotic behaviour. The developmental process determines, for better or worse, how libidinal energy will be directed in each individual. This is an unflattering account of human nature but we should not look to science for flattery. The point is that Freud's theory calls on no forces that are not already active in the evolution of lower animal species. Anyone who does not accept his account has either to argue for an alternative, working within the same constraints, or to postulate new forces specific to the formation of human (as opposed to animal) nature. Today, not many people take the latter course. Freud proposed answers to questions that no one else has asked and some would prefer never to have been asked at all. There is no guarantee that genuine alternative answers would be more flattering to human *amour propre* than Freud's were.

Following Freud, personality theories proliferated (Maddi 1989). Freud believed that successful therapy required recall into awareness of forgotten traumas of early childhood development, to redirect libidinal energy that had been misdirected or had failed to achieve any direction. The therapy was long, expensive and frequently unsuccessful. Carl Rogers (1961) proposed as an alternative a form of 'non-directive' therapy. In ordinary discourse between persons, an opinion expressed by one party is conventionally met with agreement or disagreement by the other party. Where the opinion concerns a personal predicament of the one (who knows more about it than anyone else), it is unlikely that either agreement or disagreement will persuade them to change it. Non-directive (or 'client-centred') therapy encourages the client to express opinions but the therapist avoids expressing either agreement or disagreement. The clients, not receiving the usual reinforcement, may then be inclined to review and perhaps modify their opinions for themselves. Unfortunately, Rogers later reverted to a form of directive therapy, conducted in small groups, on the (possibly mistaken) assumption that most human beings have it in them to function as therapists.

A second major development was the attempt to apply learning-theory principles (that is, behaviourism) in a clinical context; in which the client's behaviour is modified by manipulation of reinforcement by the therapist. Alcoholism may be treated by administering a drug that makes patients violently sick if they subsequently take alcohol. Phobic anxiety may be treated by teaching the patient to relax completely (a physical state incompatible with anxiety) and introducing the feared object gradually over a number of therapy sessions. All these treatments try to extinguish the learned connection between some unwanted piece of behaviour and its present, painful or pleasurable, outcome.

Treatment of personality disorders is now almost always eclectic, drawing on more than one therapeutic tradition. Since the object is to benefit the client, any treatment that works is, in principle, justifiable. The age of grand, overarching theories of personality has perhaps passed. True or false, they turn out to have few useful consequences - human nature is simply too complex.

Ptolemy (*c.* AD 100-70)

The astronomer Ptolemy was one of the leading scientific figures of Graeco-Roman antiquity. His contributions to philosophy lie in his reflections on scientific activity. In knowledge, he distinguishes a perceptual stage, which provides the natural link between knowledge and things, from a further, rational stage, governing the transition to science. The move towards science consists of the progressive distinction between concepts, initially acquired through experience and methodical observation. Many components of his thought are derived from earlier philosophy, but he excludes those aspects which bear on more general philosophical issues.

Ptolemy - Claudius Ptolemaeus - probably lived at Alexandria. His *Mathematical Composition*, better known under its Arabic title the *Almagest*, offered a complete treatment of celestial phenomena, based on the assumption of geocentricism and employing mathematical models founded on uniform circular motions. It is one of the greatest works in the history of science. In addition, he wrote monographs on astronomical themes and comprehensive treatments of nearly every science with a high mathematical content: optics, harmonics, geography, astrology. In all these areas his writings remained standard reference works for centuries.

His philosophical work, *On the Criterion and Commanding-Faculty*, concentrates on the act by which one attains knowledge of real objects - primarily sensible ones. The act consists of two stages: (1) by means of the sensory apparatus the soul is affected and perceives this; (2) the intellect reads the perception, translating it into the terms of reason (see Logos). This distinction between a perceptual and a rational stage does not make the translation artificial or arbitrary. The sensory apparatus is a set of *natural* tools, each with a proper, normal and natural mode of application which already contains a rational and conceptualizable principle. As a result, the perception yields a determinate reading, translatable into rational terms.

This theory is located within a general epistemology. The intellectual and perceptual faculties (the latter subdivided into five senses) both deal with the same domain - things and their properties. Intellect (see Nous) develops only in human beings and is later than the perceptual faculty. Starting from the data of individual perceptions, intellect comes to grasp both the functioning of the senses and aspects of external things. By means of memory, these aspects are detached from the original perceptual encounter, to form the stock of concepts used in the reading of percepts. Subsequently they become the object of separate reflection by the intellect, as by progressively articulating them it classifies things, through genera and species, all the way down to indivisible particulars. Underlying this task are certain concepts - same/different, equal/unequal, similar/dissimilar - which Ptolemy calls the intellect's proper objects, not derived from perceptual activity at all. Anyone who does not progress beyond the stage of focusing on objects in isolation remains at the level of 'opinion'. The scientific frame of mind is achieved by incorporating one's opinions into the rational order.

While perception is incontrovertible regarding effects on the soul, being a direct awareness of these, it can nevertheless be deceptive regarding its own external cause. It indicates this cause, without being the judge of the indication's correctness. However, that does not reduce perceptions of things to mere subjective experiences, because (1) the natural basis of cognitive activity guarantees that in normal conditions it functions correctly, and (2) it is the intellect's role, through its capacity for rational translation, to act as the judge. When in doubt, the intellect can have recourse to repetition of the cognitive act. Moreover, it can organize systematic observation, and this, combined with the refinement of concepts, constitutes the path from opinion to knowledge.

If perceptions can be judged by the intellect, they must be analysable. Here Ptolemy adopts the Aristotelian distinction between special and common sensibles (see Aristotle §18), and his *Optics* (partially extant in a Latin translation of an Arabic translation) offers an analysis of vision. 'In reality' vision perceives condensed illuminated surfaces; 'immediately' it perceives the special sensibles, that is, colours; 'derivatively' the common sensibles, that is, body, size, shape, position and motion. Structurally, vision is treated in geometrical terms as a cone with its apex at the eye. Ptolemy establishes the limits of vision's powers, and its internal interrelations in perceiving its different objects. And he produces a complete typology of optical illusions, both those due to natural external conditions and those due to inadequate understanding of vision's workings. The *Optics* perfectly illustrates how Ptolemy's overall conceptual framework can encase a scientific inquiry combining empirical observation, conceptual analysis and mathematics.

Ptolemy rarely invokes earlier philosophical discussions. Nevertheless, his thought and terminology include elements from every preceding major philosophy. His strategy is to extract from the tradition whatever he needs in order to define his scientific activity in its various aspects. But his principal philosophical hallmark is his way of ranking the perceptual and rational stages in knowledge, which enables him to build out of natural cognitive processes a path which, under the guidance of reason, leads to science. For any science to travel this path (as distinct from an individual's acquisition of a scientific disposition) takes longer than a human life span. He can thus, in the *On the Criterion and Commanding-Faculty*, deliberately ignore the classic Stoic -Academic debate (see Arcesilaus §2; Stoicism §§12-13) on the criterion (despite frequently drawing material from it): he may take it to bear only on practical philosophy, not philosophy of science.

According to P. Duhem's (1913) classic thesis, Ptolemy assigned a purely instrumental value to the mathematical models used in his scientific work: they helped him organize his observations and derive predictions from them, without any pretence of referring to physical fact (see Duhem, P.M.M. §4). In the *Almagest* Ptolemy certainly sometimes *uses* his models in that way. Nevertheless, his explicit defences of them do not sound instrumentalist, but normally rest on physical presuppositions. Moreover, in his *Planetary Hypotheses* he constructs an intricate system of nested corporeal spheres, and these match the components of the *Almagest*'s models. Finally, instrumentalism seems scarcely compatible with his theoretical pronouncements in the *On the Criterion and Commanding-Faculty* and the *Optics*. We may say that Ptolemy took a realist view, but that, given the absence in his day of a clearly formulated instrumentalist position, his implicit realism is not so rigorously defined as to prevent his adopting a more dismissive tone when it suits him.

Public interest

The concept of the public interest can be used in a wide variety of ways, and this has led many to say that it is devoid of meaning. However, the concept enables us to evaluate the tendency of policies and institutions to promote the interests of the members of a society considered in their broadest relations, for example in connection with policies to promote public health. In this sense it has significance. Historically, the concept of the public interest has drawn upon three main traditions of thought: the utilitarian idea of utility maximization; the tradition of civic republicanism; and Rousseau's idea of the general will. Nowadays, three main ways of meeting the public interest are distinguishable: the supply of certain indivisible goods like clean air; the preservation of identity-conferring social goods like a distinctive language; and the balancing of competing considerations in the making of public policy. Although the provision of goods in the public interest may be associated with injustice, there is no reason in general to think that justice and the public interest must conflict.

1 The concept of the public interest

The principle of the public interest is a broad one. Moreover, it is related to other ideas like 'common advantage', 'common good', 'public good', 'public benefit' and 'general will'. Given this wide range, it is tempting to say that the idea of the public interest is so indeterminate as to be virtually meaningless.

Despite these doubts, it is possible to identify a core sense to the term. The root idea seems to be that a policy, practice or institution is in the public interest if it is to the interest, advantage, benefit or good of some group or set of persons considered to be members of the same society. Thus, a well-functioning legal system together with an uncorrupt system of public administration will be in the public interest, by facilitating a wide range of civil and individual activities in a society.

It may turn out that a policy or practice that is in the public interest, so defined, will not be to the advantage of some subgroup in society. Does this show that all we mean by the concept is a collection of private interests? Not at all. If it would be more profitable for the Mafia to have a corrupt system of law and public administration, we may still quite properly say that there is a public interest to the contrary, since there is no way in which the minority interest could serve a more general good. For this reason, Bentham, with typical verve, called subgroups whose existence depended upon subverting the public interest 'sinister interests'.

2 Three traditions

An important influence in defining the concept of public interest has been the utilitarian tradition, in particular that strand stemming from the philosophic radicals at the beginning of the nineteenth century (see Utilitarianism). The philosophic radicals made the concept of the public interest central to their political philosophy and defined it in terms of the aggregate interests of the members of a society.

Within the tradition known as civic republicanism, by contrast, the principle of the public interest is associated with virtuous citizens upholding the institutions of a free republic, including the practices of participation in public affairs and the performance of military service (see Republicanism).

Rousseau's use of the term 'general will' forms a third tradition. According to Rousseau, the policies and practices of a society should be determined by a vote of a majority of citizens. Provided that all citizens are voting with an awareness that their choices will affect them in all the roles they occupy, the result of a majority vote will constitute the general will. In voting, citizens do not identify a pre-existing public interest, but instead define that interest in the process of choice. In this way, Rousseau hoped to combine a republican sense of virtue with a modern notion of moral autonomy (see General will §1; Rousseau, J.-J. §§1-3).

3 Modern conceptions of the public interest

The traditions listed above intermingle in modern thought in defining three varieties of meaning for the public interest.

The first sense owes much to utilitarianism and draws upon the economist's notion of a public good. Within economics a pure public good is defined as being non-rival, so that one person's consumption does not diminish

the consumption of others, and non-excludable, so that if one person in a society consumes the good, then others will as well. An example of a public good in this sense is clean air. Person A's consumption of clean air does not detract from anybody else's consumption, and if clean air is available to A it will also be available to anyone else in the society. Goods having these properties include: environmental amenity, public order, good government, a sense of fairness and obligation in contractual relations, tolerance and civic mindedness.

A familiar difficulty in the provision of such public goods is the so-called 'free rider' problem or problem of collective action (see Rational choice theory). The difficulty arises because, although it may be in everyone's interest that a public good is supplied, it may be in no particular person's interest to bear a share of the costs of supply. Since the good is non-rival and non-excludable, each individual will benefit from the existence of the good, whether or not they have made a contribution to its costs. Self-interested persons would therefore be tempted to free ride on the contributions of others, hoping that they could gain the benefit without incurring the costs. But free riding, when generalized, is collectively self-defeating, since if no one incurs the costs, the public good will not be supplied.

Various suggestions have been made for overcoming the free rider problem. A Hobbesian line of argument is that it provides a justification for the state to have coercive authority, so that it can enforce individual contributions to the supply of public goods in the public interest (Hobbes 1947). This line of argument also has affinities with Rousseau's idea that in the social contract people are 'forced to be free' in implementing the general will. Other suggestions for overcoming the free rider problem rely upon the consequences of repeated interaction among small numbers of people, in which norms of cooperation can emerge, or upon a moral education that will encourage people to internalize Kantian principles of fairness.

Public goods in this sense are instrumental, since they are compatible with widely divergent personal conceptions of the good. By contrast, the public interest may include the idea of a common good. Drawing its inspiration both from the tradition of civic republicanism and from Rousseauian/Hegelian notions of community and social identity, this formulation identifies certain irreducibly social goods that are constitutive of central human interests: a language and the cultural traditions that go with it; a sense of place and landscape for a people; the continuation of a people's identity; or popular participation in the shaping of a common political life.

The specification of the concept of a common good in this sense is central to debates between liberals and communitarians, and therefore to debates about the virtues of patriotism and the obligations of citizenship. Communitarians contest the idea that individuals in a society are bound together solely by their subscription to a common set of rules constraining the exercise of their freedom. They argue that a common social life exists prior to the formation of individuals and that notions of the right and justice have to be conceptualized so that they are consistent with a society's common good. In practice, such a view would presumably licence policies and practices that would inculcate certain patriotic virtues, for example a willingness to defend one's country in time of attack (see Community and communitarianism).

The third modern notion of the public interest is more formal than the previous two, although common in everyday political argument. Here the public interest is a balance between competing, but incompatible, goods. For example, freedom from police constraint is a good and so is personal security. To ensure personal security, it may be necessary to give the police general powers to stop people on suspicion of carrying concealed weapons. In this case two incompatible goods are set against one another, and it is sometimes said that the public interest is best promoted where a suitable balance is struck between them.

Can one define how this balancing might take place? Two methods have sought to give substance to the idea of balancing: Benthamite utilitarianism, in which the balance is struck at the point at which aggregate utility is maximized, and Rousseau's notion of the social contract, in which the balance is struck at the point of majority decision on the general will.

Both approaches are beset with difficulties, however. It is not clear that Benthamite utilitarianism can provide a weighting of utilities that does not beg the question about the value of different outcomes. The Rousseauian approach can provide little independent evidence about the terms of a social contract. In practice, despite these limitations, public policy is often made by some form of balancing, either by decision makers weighing the supposed advantages or disadvantages of various alternatives or by popular decision. Thus, the principle of the

public interest as a balancing of goods has some significance, even if its meaning is difficult to state precisely.

4 The public interest and reducibility

Who or what might be the bearer of a public interest? In speaking of the public interest, it may seem as though we are identifying an entity over and above the individuals who make up a society. Methodological individualists, who assert that there is no such entity, baulk at this thought.

In the first and the third modern senses of the public interest, however, it is not necessary to abandon methodological individualism, provided we are allowed to identify the interests of non-assignable individuals. This means that the ascription of interests cannot rest solely upon the expressed preferences of actual individuals, but must instead presuppose that there are certain interests sufficiently widely shared to ascribe them to a wide range of persons whoever they might be (see Needs and Interests §1).

The second sense of the public interest, involving the notion of a common good, raises more complicated questions. Languages and cultures are themselves non-reducible entities. Their preservation and advancement may therefore seem to require a non-reducible sense of the public interest. However, this appearance is misleading if we think that the reason why such entities should be preserved is to advance the wellbeing of those individuals who will be members of a certain society.

5 Justice and the public interest

The notion of the public interest is distinct from that of justice, since we can quite sensibly say that a practice is in the public interest but that the costs of maintaining it are unfairly distributed among the population. For example, a population might need to save water in a drought, but it might be unfair not to exempt market gardeners, whose livelihood depends upon a ready supply of water, from the restrictions.

In recent discussions of justice, it has been common to contrast justice and utilitarian conceptions of the public interest (see Justice §3). Thus, it has been urged that a commitment to an impartial consideration of the public interest cuts across the special moral obligations that individuals owe to one another in justice, and can give weight to illegitimate preferences based upon prejudice that would discriminate against classes of individuals.

It is certainly true that without some principle of equality an appeal to aggregate interests can disadvantage particular individuals. However, some aggregate balancing seems called for where general interests of similar importance are set against one another, for example freedom of movement and freedom from arbitrary attack. In these contexts, the concept of the public interest seems central to our ability to balance interests without being opposed to justice.

Pufendorf, Samuel (1632-94)

Pufendorf was the first university professor of the law of nature and nations. His De iure naturae et gentium (On the Law of Nature and Nations) (1672) and De officio hominis et civis iuxta legem naturalem (On the Duty of Man and Citizen according to Natural Law) (1673) greatly influenced the handling of that subject in the eighteenth century. As a result Pufendorf has been recognized as an important figure in the development of the conception of international law as a body of norms commonly agreed to have universal validity by sovereign states. He regarded himself as an exponent of a new moral science founded by Hugo Grotius which transformed the natural law tradition by starting from identifiable traits of human nature rather than ideas about what human beings ought to be.

Pufendorf began his higher education by enrolling to study theology at the University of Leipzig in 1650. He soon found philosophy, history and law more to his taste. Moving to Jena in 1656, he discovered the brand of philosophy that interested him most in the works of Grotius, Descartes and Hobbes. In 1658 he was made tutor to the family of the Swedish ambassador in Copenhagen, only to be imprisoned when war recommenced between Sweden and Denmark. The ambassador escaped to Holland, where Pufendorf eventually joined him, taking the opportunity to further his studies at the University of Leiden. In 1661 he accepted a chair at Heidelberg, moving in 1668 to a new appointment at Lund. When the Danes besieged Lund in 1676 Pufendorf was called to Stockholm by Charles XI and made a privy councillor, secretary of state and Swedish historiographer royal. A decade later he received similar appointments in Prussia. He died after a brief visit to Sweden in 1694.

The parallels between the lives of Pufendorf and Grotius are striking: both became engaged in public service, particularly on Sweden's behalf; both took advantage of a period of imprisonment to develop their ideas; both wrote on a range of subjects - legal, historical and religious as well as philosophical. Where their paths most clearly diverged, however, was in Pufendorf's pursuit of a career as a university teacher. Though his *Elementa iurisprudentiae universalis (The Elements of Universal Jurisprudence)* (1660) was written after his connection with a Swedish embassy had resulted in his incarceration, it built on his earlier studies at Jena and secured his later appointment at Heidelberg. Both there and at Lund Pufendorf was employed as Professor of the Law of Nature and Nations to teach the doctrines adumbrated in Grotius' *De iure belli ac pacis (The Law of War and Peace)* (1625). Pufendorf produced a further exposition of those doctrines in his major work *De iure naturae et gentium (On the Law of Nature and Nations)* (1672) and its hugely influential epitome *De officio hominis et civis iuxta legem naturalem (On the Duty of Man and Citizen according to Natural Law)* (1673).

It is on these three treatises that his reputation as a philosopher rests. He has been hailed with Grotius as an early theorist of a new international order in which a society of sovereign states was formed by the common recognition of rules governing their relations with each other. More recently his own perception of himself as an exponent of a new moral science founded by Grotius has been revived. There can be little doubt that Pufendorf's widely disseminated works contributed greatly to the impact of this modern, post-sceptical, version of natural law theory on philosophers of the eighteenth century. Problematic is the extent to which he made a significant contribution to the substantial development of the theory.

Pufendorf was more conscious than Grotius of his role as an exponent of a distinctive discipline. Hitherto the study of universal jurisprudence had been the preserve of two academic elites: lawyers and theologians. Pufendorf insisted that the discipline of law was properly concerned with the civil laws regulating the conduct of citizens in specific states. Those laws turned on the legislator's will and, unlike natural laws, could not be ascertained by unaided reason. Similarly, the divine laws with which moral theologians were properly concerned had to be learned through revelation of the legislator's will. They regulated the thoughts as well as the deeds of Christians whose citizenship was celestial. By contrast, Pufendorf's discipline used reason to discover the laws that governed the deeds of people of all creeds in earthly societies (see Legal positivism; Sovereignty).

If Pufendorf was led to this clearer demarcation of the provinces of ethics, law and theology by his involvement in university teaching, the altered circumstances of public life in his time may explain a second way in which he went beyond Grotius. Writing against a background of devastating warfare, Grotius had tried to discover a basic moral consensus from which it could be shown how human beings might achieve peace and security through the

formation of societies. Writing after the Peace of Westphalia brought relative stability to Europe, Pufendorf was able to proceed beyond Grotius' minimalist account of natural law and to specify more fully the duties people owed to each other once they had formed societies. His exposition was therefore more extensive than Grotius' and more obviously relevant to readers who could take for granted the peace and security Grotius had sought. Later natural law theorists were to develop this trend further (see Natural law §5).

Both in defining the scope of his discipline and in exploring its contents, Pufendorf made significant adjustments to its conceptual apparatus. Grotius had still written in an Aristotelian way about human beings having an innate tendency towards life in society. In place of this essentialism Hobbes had depicted humans as beings entirely motivated by self-interest. Both authors had identified in each person's interest in self-preservation a natural right to do what each person saw fit for their own preservation. Pufendorf agreed with Grotius that human beings were sociable, but followed Hobbes in basing his claim on identifiable traits imposed on human nature by God rather than on any innate disposition in humans. Having done so, he was able to take human sociability as the foundation of all the duties of humanity and to talk more in terms of duties than of rights. For Pufendorf all rights were simply correlative to duties.

Purgatory

According to Roman Catholic teaching, purgatory is the place or state of purification after death in which those who die in a state of grace (and hence are assured of being saved) make expiation for unforgiven venial sins or endure temporal punishment for mortal and venial sins already forgiven. The concept evolved to resolve the theological confusion about the state of souls between personal death and the general resurrection and Last Judgment, to explain what happens to those persons who repent before death but do not live long enough to do penance for their sins, and to make intelligible the widespread practice of praying for the souls of the departed. The doctrine developed in conjunction with a 'high' Eucharistic theology, according to which all the faithful departed take part in the liturgy of the Church. The idea of purgatory is therefore intimately connected with Christian ideas of sin, judgment, retributive punishment, the communion of saints and the idea that salvation occurs in history. It was rejected by the Reformers and, in the second half of the twentieth century, interest from Catholic theologians has waned. Nevertheless, some modern Protestant thinkers have defended the concept as an intermediate phase in salvation.

1 The development of the idea of purgatory

Purgatory is not explicitly mentioned in the Bible, but its supporters have thought it is implied in the apocryphal 2 Maccabees 12: 39-45, where Judas Maccabaeus makes propitiation for the sins of those in his army who died in battle upon discovering that they had worn pagan amulets. Several New Testament texts have also been interpreted as indirectly referring to purgatory; an example is Matthew 12: 31-2, which refers to the sin 'which will not be forgiven either in this world or in the world to come', perhaps implying that expiation is still possible after death.

The custom of offering prayers for the dead in the early Church was widespread and quickly became established practice in the liturgy. With the exception of Aerius, a fourth-century presbyter of Pontus mentioned by Augustine as a heretic, there is no evidence of dissent or hesitation on the matter of prayers for the baptized dead. Hints of the belief in a place for which expiation for sin can be made after death probably appear first in the writings of Tertullian. His contemporary, Clement of Alexandria, more explicitly refers to a place where those who have repented on their deathbed but have not had time to do penance will be sanctified after death by purifying fire. Basil, active in the third to fourth centuries, wrote in a homily on Psalm VII that those with 'any stains or relics of sin' after death 'should be detained'. At the end of the fourth century, Jerome wrote to his friend, the senator Pammachius, on the death of the latter's wife, praising him for venerating her by giving alms, 'knowing that it is written: as water extinguishes fire, so does alms, sin' (Letter LXVI).

The views of Augustine are important, because his subtlety and clarity of thought have carried his influence on Christian philosophy into the present era, but his position on purgatory is not unequivocal. Upon the death of his mother, St Monica, Augustine offered prayers for the repose of her soul, but he is reticent on the question of the nature of purgatory and of a purgatorial fire and treats it tentatively in the *Enchiridion* (chaps 69-70). However, he appears more confident in *De civitate Dei (The City of God)*:

> But temporary punishments are suffered by some in this life only, by others after death, by others both now and then; but all of them before that last and strictest judgment. But of those who suffer temporary punishments after death, all are not doomed to those everlasting pains which are to follow that judgment; for to some, as we have already said, what is not remitted in this world is remitted in the next, that is, they are not punished with the eternal punishment of the world to come.
>
> (XII: 13)

More importantly for the later development of the doctrine of purgatory, Augustine, in the *Enchiridion*, lays down rules for the use of suffrages, as prayers and alms offered for the dead were called. The first rule is that suffrages benefit not all the dead, but only those who are neither damned nor already in heaven; it is too late for the former, and the latter do not need it. The second rule is that a person qualifies for suffrages only in life. Bernstein (1993) says that these two rules came to guide the Church in regulating devotion of the living for the dead. As time went on they were interpreted as permitting the dedication of good works as well as prayers to expiate the sins of the deceased. Thus believers endowed charitable institutions and houses of prayer, and upon this basis the practice of indulgences arose.

2 The emergence of the doctrine and its decline

Atwell (1987) argues that important changes in the Church during the sixth century augmented the development of the idea of purgatory into a full doctrine in the work of Pope Gregory the Great. These developments included the systematic ordering of the penitential system within the Church, the differentiation of mortal and venial sins, and the emergence of a Eucharistic theology in which the faithful departed were commemorated and the saints petitioned for intercession. These liturgical practices were linked with the doctrine of the communion of saints, whereby the Church was understood as involving fellowship between the living and those among the dead who are saved and who therefore remain part of the Church.

Le Goff (1981) claims that the doctrine was really born in the twelfth century, when a great intellectual and moral revolution changed the way people thought about sin and profoundly altered penitential practices. This revolution started with Anselm of Canterbury (§8), whose investigation into the voluntariness necessary for sin in the *Cur Deus homo* (completed 1098) led to an era of examination of the notions of personal responsibility, guilt and punishment. This gave rise to the distinction between guilt (*culpa*) and the debt of punishment (*poena*), a distinction at the heart of the logic of purgatory. *Culpa* can be pardoned through contrition and confession, but *poena* is effaced only by 'satisfaction', that is, by completing a penance. This distinction appears in Aquinas, who says that if a soul has repented and been forgiven, but owes a debt to divine justice at death, this delays the soul's flight to heaven and makes a prior purgation obligatory (*Summa theologiae* IIIa, q.69, a.2, corpus). Aquinas maintained that souls in purgatory accept their suffering voluntarily, understanding that they are in the last stage of preparation for the beatific vision (see Heaven §3).

The official teaching of the Roman Catholic Church was defined at the Councils of Lyons (1274) and Florence (1439) with the intent of reconciling the Greek Christians, who objected to the idea of material fire and the distinction between *culpa* and *poena*. These councils avoid the term *purgatorium* for the sake of the Greeks, but speak of a purification after death for those souls 'who died truly penitent in the love of God before satisfying for their sins through worthy fruits of penance' (Denzinger and Schoenmetzer 1967: 464). There is no mention of fire. Even within the Latin Church there were disagreements on the nature of the pains of purgatory, with some emphasizing the pain of loss - the consciousness of being separated from God, albeit temporarily (and some even maintaining that such pain constitutes the entire pain of purgatory), while others emphasized the pain of sense - physical pain. Aquinas maintained that the pain of sense in purgatory comes from actual fire which is more painful than the greatest sufferings of this world, but later scholastics such as Suárez were inclined to doubt any comparison between the sensory pains of this world and those of purgatory. While the suffering in purgatory was often vividly described in imaginative literature, sometimes the hopefulness of purgatory was stressed instead. In the *Il Purgatorio* of Dante's *Divina Commedia*, purgatory is a mountain that reaches up to heaven. Dante describes how the desire for heaven makes souls fly towards God, causing the mountain to tremble constantly with a joyful thunderclap marking the arrival of each soul into paradise.

The existence of purgatory was denied by the Reformers, such as Luther, who usually also questioned the utility of prayers for the dead. In reply, the Council of Trent in 1562 proclaimed the propitiatory value of the sacrifice of the Mass even for the dead, but otherwise said only that 'Purgatory exists, and the souls detained there are helped by the prayers of the faithful' (Denzinger and Schoenmetzer 1967: 998, 983). No mention was made of the place or duration of purgatory, or of the nature of purgatorial punishment.

Interest in purgatory has declined during the latter half of the twentieth century, accompanied by a decline in interest in most of the concepts with which purgatory has been associated. The documents of Vatican II, the ecumenical council called by Pope John XXIII in the 1960s, do not mention purgatory at all, although prayers for the dead continue to be offered in liturgical services. Occasionally, however, Protestant theologians have offered defences of the existence of purgatory. Hick (1976) speaks approvingly of an intermediate state between death and heaven, but rejects many of the traditional elements of purgatory, believing that the person-making process can continue beyond the grave (see Evil, problem of §4). Brown (1985) has argued that there are conceptual problems with the idea that a human being makes an abrupt transition between a state of moral imperfection at death and a state of moral perfection in heaven. He argues that we know and identify ourselves only through continuity with our past, but a person who is suddenly morally perfected would have no reasonable grounds for believing themselves to be the same person whose past they 'remember'. Brown concludes that if there is a heaven, there

must also be a purgatory that provides a gradual transition to a perfected state. Walls (1992) is another Protestant theologian who accepts the idea of purgatory as part of the logic of the Christian conception of salvation.

Putnam, Hilary (1926-)

Putnam's work spans a broad spectrum of philosophical interests, yet nonetheless reflects thematic unity in its concern over the question of realism. A critic of logical positivism, Putnam opposed verificationism and conventionalism, arguing for a realist understanding of scientific theories. He rejected the traditional conception of meaning according to which speakers' mental states determine meaning and consequently, reference, and put forward a conception of meaning on which external reality, for example, what one talks about, contributes essentially to meaning. Further, citing what he called the division of linguistic labour, Putnam saw the conferring of meaning as a social rather than an individual enterprise. In response to the relativistic challenge that the incommensurability of different theories precludes any possibility of intertheoretical dialogue, Putnam invoked a causal theory of reference construing reference as relatively insensitive to theoretical variation, so that the continuity and rationality of science and communication are upheld. The Copenhagen interpretation of quantum mechanics posed yet another difficulty for realism. Putnam saw quantum logic as an alternative which was compatible with realism, and argued that logic, like geometry, can be revised on the basis of empirical considerations. In the philosophy of mind, Putnam proposed functionalism, the view that mental states are characterized by function rather than material constitution. Putnam also made a substantial contribution to mathematics through his work on the insolvability of Hilbert's tenth problem.

In 1976, Putnam launched an attack on the coherence of the view he termed 'metaphysical realism'. Arguing that relativism and scepticism are disguised forms of metaphysical realism, and likewise incoherent, he suggested an alternative, referred to as 'internal realism'. Clarification of this position and its viability as a third way between realism and relativism is the focus of Putnam's later writings, and of much of the criticism they have incurred.

1 Life

Born in Chicago in 1926, Putnam spent his early years in France. His father, Samuel Putnam, was a well-known writer and translator, an active communist, and a columnist for the *Daily Worker*. Along with Noam Chomsky, Putnam majored in the emerging field of linguistic analysis at the University of Pennsylvania (and also in philosophy and German). His graduate studies were divided between Harvard, where he studied with Quine, Hao Wang, C.I. Lewis and Morton White, and UCLA, where he wrote his Ph.D. dissertation on the concept of probability under the supervision of Reichenbach. In 1953 he moved to Princeton, made the acquaintance of Carnap and, receiving informal instruction from Kreisel, worked intensively on mathematical logic. He has been at Harvard since 1965. Putnam actively protested against the Vietnam War, and was also active in Students for a Democratic Society (SDS) and The Progressive Labour Party, a Maoist group. Around 1972 he became disillusioned with communism. Since Putnam saw his early realism as embodying some of Engels' insights, it seems plausible that this turn affected his philosophical development. Later, he became interested in the study and practice of his Jewish heritage.

2 Realism

Putnam criticized such basic elements of logical positivism as the verificationist theory of meaning, reductionism and conventionalism, while sharing the positivists' interest in and respect for natural science (see Logical positivism §2). He maintained that realism is the only philosophy that does not render the success of science a miracle (see Realism and antirealism; Scientific realism and antirealism §3). His argument from success is presented as structurally similar to hypothetico-deductive arguments within science: realism provides the best explanation for the success of science in the same way atoms and genes provide explanations for observable phenomena. However, this analogy is problematic in that it is purely formal. Realism has no empirical import beyond that of its alternatives, a desideratum scientific hypotheses must meet.

Putnam's criticism of conventionalism is developed in *An Examination of Grünbaum's Philosophy of Geometry* and *The Refutation of Conventionalism*. On the Reichenbach-Grünbaum conception, the core of the transition from Newtonian to relativistic mechanics is a new definition of the spacetime metric. The definition chosen is a matter of convenience, not of truth (see Conventionalism §1). According to Putnam, however, meaning change is only part of the story; theoretical concepts have explanatory import, and must be anchored in a theory that meets both empirical and non-empirical constraints. There is, therefore, much less freedom than the conventionalist alleges.

Putnam raises a similar objection to Quine's celebrated indeterminacy of translation thesis (see Quine, W.V. §9). Here, as in the case of conventionalism, underdetermination is an illusion created by considering an unreasonably limited set of constraints. Once we recognize coherence, simplicity, and so on, as constraints on translation or theory-construction, conventionality and indeterminacy vanish.

3 The meaning of meaning

Putnam faults the traditional theory of meaning for being individualistic rather than social, and for neglecting the contribution of external reality to meaning. He construes the standard theory as based on the two assumptions that to know a term's intension is to be in a particular psychological state and that intension determines extension. Hence, it is argued, speakers who are in the same mental state when uttering a word share both its intension and its extension.

Putnam uses the twin earth (TE) thought experiment to attack this theory. TE resembles earth down to the smallest detail except that the liquid functioning as water, and called 'water', on TE is not $\mathrm{H_2O}$, but a different chemical compound. Since there is no reason to ascribe different mental states to a person using 'water' on earth, and their counterpart on TE, or, at least, there was no such difference prior to the emergence of chemistry as a science, this constitutes an example of people using the same word when in identical mental states, but ascribing different meanings to it: one refers to water, the other to the TE equivalent. One need not, however, travel as far as TE to find examples of similar mental states differing in extension. Putnam testifies that he is unable to tell a beech from an elm: his mental image of the two is the same, yet the extensions, and the meanings, of 'elm' and 'beech' are quite different in his idiolect. Can Putnam refer to an elm though unable to identify one? His answer introduces the concept of the division of linguistic labour: it is sufficient that experts can distinguish an elm from a beech, and unnecessary that each member of the linguistic community be able to do so.

The assumption underlying the TE example is that words like 'water' always refer to the stuff we call 'water' in the actual world. Though it is neither analytic nor even irrevisable that water is $\mathrm{H_2O}$, the extensions of 'water' on TE and on earth cannot be identical. To complete the account of meaning, one has to address the question of how extension is actually fixed. These aspects of Putnam's conception are related to Kripke's work on reference and rigid designation (see Kripke, S.A.; Proper names; Reference §2), but while Kripke was thinking mainly of proper names, Putnam's concern is the meaning of scientific terms. If the extensions of these terms are fixed by the theories in which they figure, then extensions will be liable to change with theoretical change. This argument can be taken as an encapsulation of Kuhn's relativism: different theories refer to different entities, and are therefore incommensurable (see Incommensurability). Viewing it as a *reductio ad absurdum* of the theory of meaning on which it rests, Putnam recommends replacement of this theory with a variant of Kripke's causal theory of reference that emphasizes not only the causal relation between speakers and what they refer to, but also such social and pragmatic factors as shared stereotypes, reliance on experts, discretion and charity (see Content: wide and narrow).

4 The philosophy of quantum mechanics

Heisenberg's uncertainty principle imposes a limit on the precision with which the values of certain pairs of physical parameters, such as position and momentum, or two spin components, can be measured simultaneously. On the Copenhagen interpretation, this principle implies that it is meaningless to ascribe simultaneous sharp values to such pairs of physical parameters, whether or not they are actually being measured. Since, however, when any one magnitude is measured separately, a sharp value is obtained, it appears that it is measurement itself which creates the transition, better known as the collapse, from the indeterminate to the well-defined state. If so, measurement does not reflect a state objectively existing prior to measurement, but points to a state of its own creation (see Quantum measurement problem). Both the inference from the impossibility of measurement to the meaninglessness of concepts and the non-classical understanding of measurement, offend the realist. In *The Logic of Quantum Mechanics*, Putnam proposed overcoming these difficulties by adopting a nonclassical logic first suggested in the context of quantum mechanics (QM) by Birkhoff and von Neumann in 1936, and developed by Finkelstein in the 1960s. The suggested logic is non-distributive - from $p \cdot (q_1 \vee q_2)$ we cannot, in general, conclude that $p \cdot q_1 \vee p \cdot q_2$. If *p* states that the system has a well-defined value *p*, of a physical magnitude P, and $q_1, q_2, \ldots, q_n$ describe all possible values of an incompatible quantity Q, then the uncertainty principle entails that $p \cdot q_i$ is false for any *i*. Yet, assuming that *p* obtains, (ascertained by measurement, say) we cannot conclude, as we classically would, that $q_1 \vee q_2 \vee \ldots \vee q_n$ is false. In fact, while $p \cdot q_i$ is a quantum logical contradiction,

$q_1 \vee q_2 \vee ... \vee q_n$ is a quantum logical tautology. The magnitude Q always has a well-defined value, which its measurement will reveal, and no collapse is called for (see Quantum mechanics, interpretation of; Quantum logic).

In light of the traditional gulf between factual and logical truth, the idea that logic can be revised on the basis of empirical considerations is revolutionary. Putnam saw this situation as analogous to the merging of physics and geometry into an interdependent whole in the framework of general relativity.

Quantum logic raises several questions. First, it is not clear that it is a logic, a way of reasoning, rather than a calculus that happens to fit the structure of the Hilbert space of QM. Second, the idea that one can save realism by rejecting classical logic, generally seen as constitutive of realism, seems paradoxical. Though intended to strengthen the analogy with logic, Putnam's operational definition of the quantum-logical operators obscures the connection to realism. Third, work on the foundations of QM by theorists such as Kochen and Specker, and Bell, put unbearable strain on the realist interpretation of QM (see Bell's theorem). Indeed, in *Quantum Mechanics and the Observer*, when Putnam had already moved away from his early realism, he assumed a verificationist understanding of quantum logic. The main point of that paper, however, is to argue for yet another interpretation of QM - perspectivism, attributed by Putnam to von Neumann. Like quantum logic, perspectivism is a way of avoiding the collapse of the wave-function upon measurement. Collapse, on this interpretation, is not a physical process but an epiphenomenon created by the shift from one perspective to another. Thus, when a system M performs a measurement on another system S, we can either view M as interfering with S from without, inducing a collapse of the wave-function of S, or view S and M as a unified system obeying QM, and the external observer as interfering with it and making its wave-function collapse. Ultimately, Putnam argues, different perspectives are empirically equivalent and congruent with the predictions of QM; hence, they are equally legitimate. But perspectives exclude each other in the sense that statements belonging to different perspectives cannot be combined to form a quantum state. Realism can be sustained within each perspective, but not across perspectives. Though this seemed an attractive way to retain 'internal' realism while forgoing metaphysical realism, upon realizing that, in some cases, different perspectives are not empirically equivalent Putnam became dissatisfied with perspectivism.

5 Mathematics and necessary truth

Putnam did significant work in mathematics, collaborating with Martin Davis and Julia Robinson in the late 1950s on proving the unsolvability of Hilbert's tenth problem, which sought an algorithm deciding the solvability of diophantine equations. The proof was completed by Yuri Matiyasevich in 1970.

The nature of logical and mathematical truth has been one of Putnam's ongoing concerns, yielding several different positions. Throughout, he rejects the standard alternatives, platonism and conventionalism. The former, is, he maintains, given twentieth-century physics, obsolete; the latter, empty: as Carroll, Wittgenstein and Quine pointed out, conventions cannot ground logic because logic is required for their application (see Mathematics, foundations of). In 'It Ain't Necessarily So', Putnam proposed replacing necessary truth with the more flexible, context-dependent notion of relative necessity, in line with his suggestion, raised regarding QM, that logic is empirical. Later, in 'Analyticity and Apriority', he argued that at least some logical truths are constitutive of rationality and, as such, cannot be rationally criticized or revised. This view is further elaborated in *Rethinking Mathematical Necessity*, where Putnam represents logical truths as 'formal presuppositions of thought' rather than as truths in the ordinary sense (see Analytic and synthetic).

6 Functionalism

In a series of papers beginning in 1960, Putnam proposed a fresh approach to the philosophy of mind, functionalism, seeking to secure the autonomy of mind without positing a non-physical mind-substance. ' The question of the autonomy of our mental life does not hinge on and has nothing to do with that all too popular…question about matter or soul-stuff. We could be made of Swiss cheese and it wouldn't matter' (1975b: 291). What matters, Putnam argued, is functional organization. Putnam's guiding analogy for functional organization was the computer (Turing machine). Evidently, different machines need not share the same hardware to carry out the same computation. Similarly, Putnam claimed, pain-states, or jealousy-states, can be functionally alike though physically different. In other words, each pain-token has a physico-chemical realization, but no reduction of the type, pain, to a given physico-chemical state is assumed. The computer analogy suggested that

mental states are computational states, characterized syntactically, the projected research programme being to provide the ’software’ for their interaction.

In the late 1970s, Putnam began to reconsider this proposal. First, there were considerations of meaning (§3). Thinking of something seems like a simple enough example of a mental state, but if, as Putnam argued, ‘meanings just ain’t in the head’, then meanings cannot be identified with internal computational states. The response of some theorists, notably Fodor and Block, was to use the distinction between narrow and wide content, presented by Putnam in The Meaning of Meaning, to save the computational picture. While acknowledging the contribution of physical and cultural environment to meaning in the wide sense, they held on to computationalism with respect to meaning in the narrow sense. Putnam’s concern over intentionality led him to reject this solution. As he argued in *Representation and Reality*, narrow-content computationalism is still an attempt to reduce the intentional to the non-intentional. But since even the ascription of meaning in the narrow sense involves interpretation, the attribution of beliefs, charity and reasonableness, eliminating intentionality is untenable. Functionalism had conceived the computational level as autonomous, that is, irreducible to, even if supervenient on, the physico-chemical level. Putnam’s critique of functionalism makes an analogous point with regard to the autonomy of the mental *vis-à-vis* the computational (see Computational theories of mind; Functionalism; Reductionism in the philosophy of the mind).

7 The incoherence of metaphysical realism

In 1976 Putnam’s philosophy underwent a major shift; rejecting what he referred to as ‘metaphysical’ realism, he adopted ’internal’ realism in its stead. The attack on metaphysical realism, first presented in the final chapter of *Meaning and the Moral Sciences* (1978) is elaborated on in *Models and Reality* and in *Reason, Truth and History* (1981).

Just as establishing the objectivity of reference was central to Putnam’s earlier realism, the dispersion of reference into a plurality of possible relations is at the heart of his later criticism. The argument draws on model-theoretic considerations. The Löwenheim-Skolem theorem entails that a first-order theory, rich enough to contain arithmetic, does not determine its models up to isomorphism (see Löwenheim-Skolem theorems and nonstandard models). Putnam extrapolates: even an ideal theory of the world, complying with all empirical and theoretical constraints, will not define a unique model, that is, a unique reference relation. In particular, causality, previously seen as anchoring language in reality, now becomes just another relation, and hence open to interpretation.

Putnam’s point is not to embrace scepticism. His argument is that both the metaphysical realist who purports to have a theory of everything, including the ’correct’ reference relation, and the sceptic who undertakes to refute that theory, are making the same mistake - they are assuming a non-existent vantage point external to any language or description-scheme. From the internal perspective, questions about reference cannot arise, ’chair’ refers to chairs, ’cherry’ to cherries. ‘ To speak as if *this* were my problem, "I know how to use my Language, but, now, how shall I single out an interpretation?" is to speak nonsense. Either the use *already* fixes the "interpretation" or *nothing* can’ (1983: 24).

Another argument against scepticism is found in *Reason, Truth and History* (1981), where considerations of reference and intentionality lead Putnam to conclude that the sceptic’s favourite fantasy - that we are all brains in a vat - is self-refuting (see Scepticism). The repudiation of scepticism is a recurrent theme uniting Putnam’s earlier and later work. The strategy, however, changes; Putnam’s responses to Quine, who has also invoked the Löwenheim-Skolem theorem, illustrate these. Whereas Putnam initially tried to reduce indeterminacy by increasing the number of constraints on an adequate translation, he later came to see the problem itself as a sceptical variation on a misguided metaphysics.

8 Internal realism

Internal realism is also referred to by Putnam as ’pragmatic’ or ’natural’ realism. Like the American pragmatists, Putnam holds that commonsense realism, which he respects, requires no ’deeper’ philosophical foundation. He also follows pragmatism in rejecting the fact/value dichotomy, and opposes moral relativism as firmly as he opposes cognitive relativism (see Pragmatism). A critic of reductionism and naturalism, he maintains that there are forms of nonscientific knowledge and that reason and morality cannot be naturalized. He distances himself from

’end of philosophy’ philosophies, and seeks to renew philosophy so as to reconnect it with human challenges and aspirations.

Internal realism is meant to avoid the pitfalls of both metaphysical realism and relativism, but Putnam has been accused of slipping back into these polar positions. At one point he was close to identifying internal realism with verificationism, with long-term warranted assertibility replacing the notion of truth. Later he rejected this view, as well as other attempts to eliminate truth.

While a long philosophical tradition sees realism and antirealism as exhaustive alternatives, Kant, the American pragmatists, and Wittgenstein, all strove to overcome this dichotomy. Putnam identifies with the latter camp. In his earlier writings, he represented realism as a kind of explanatory hypothesis, on a par with scientific theories. Internal realism, however, is not intended to play an explanatory role. Wittgenstein’s influence, and particularly, his suspicion of philosophical theories, is perceptible here, not only in the subtle similarity between the extended Löwenheim- Skolem theorem and the rule-following paradox, but also in the change of perspective that constitutes the response to these related problems. When we realize that internal realism is not an alternative theory but a call for a change of perspective, it emerges that much of Putnam’s earlier work, far from being undermined by his later philosophy, finds its proper place within it.

List of works

Most of Putnam’s papers, and all of those cited in the text, are included in the collections - *Philosophical Papers, volumes I-III* and the two volumes edited by J. Conant. Where the title has been changed, the text cites the title appearing in these volumes.

Putnam, H. and Benacerraf, P. (eds) (1964) *Philosophy of Mathematics: Selected Readings*, New Jersey: Prentice Hall.(Introduction by the editors. Includes classic works in the foundations of mathematics and the philosophy of mathematics by leading mathematicians such as Hilbert, Brouwer and Gödel.)

Putnam, H. (1971) *Philosophy of Logic*, New York: Harper & Row.(Putnam argues for a realist position on the problem of the existence of mathematical objects.)

Putnam, H. (1975a) *Philosophical Papers*, vol. I, *Mathematics, Matter and Method*, Cambridge and New York: Cambridge University Press. (This volume contains papers on the philosophy of mathematics and the philosophy of science. It includes ‘It Ain’t Necessarily So’, which develops the notion of relative necessity, ‘An Examination of Grünbaum’s Philosophy of Geometry’, which argues against a conventionalist interpretation of the theory of relativity, and ‘The Logic of Quantum Mechanics’, advocating quantum logic.)

Putnam, H. (1975b) *Philosophical Papers*, vol. II, *Mind, Language and Reality*, Cambridge, and New York: Cambridge University Press. (This volume includes one of Putnam’s major contributions to the philosophy of language, ‘The Meaning of Meaning’, as well as ‘Explanation and Reference’ and ‘The Refutation of Conventionalism’, all of which expound a realist conception of meaning. It also includes papers in the philosophy of mind, in particular papers introducing functionalism, such as ‘Philosophy and Our Mental Life’ and ‘The Mental Life of Some Machines’.)

Putnam, H. (1978) *Meaning and the Moral Sciences*, London: Routledge & Kegan Paul. (Part One contains the John Locke Lectures, Oxford 1976, which explore the interconnections between explanation, theories of truth, and realism. Part Two marks the change in Putnam’s position from realism to ’internal realism’.)

Putnam, H. (1981) *Reason, Truth and History*, Cambridge, and New York: Cambridge University Press.(The book propounds ’internal realism’, arguing that it avoids the difficulties of metaphysical realism on the one hand, and scepticism on the other.)

Putnam, H. (1983) *Philosophical Papers*, vol. III, *Realism and Reason*, Cambridge, and New York: Cambridge University Press.(This volume reworks many of the themes previously dealt with by Putnam in the light of his new position. It includes ‘Models and Reality’, which pursues the implications of the Löwenheim-Skolem theorem; ‘Analyticity and Apriority: Beyond Wittgenstein and Quine’, which rejects some sceptical consequences of Quine’s and Wittgenstein’s positions; ‘Why Reason Can’t Be Naturalized’, which argues against naturalism; and ‘Quantum Mechanics and the Observer’, which argues for perspectivism, and abandons the earlier realist interpretation of quantum mechanics in terms of quantum logic.)

Putnam, H. (1987) *The Many Faces of Realism*, La Salle, IL: Open Court.(The Paul Carus Lectures, Washington 1985. Putnam’s ’internal realism’ is examined here in the context of American pragmatism, in particular

Peirce’s philosophy.)
Putnam, H. (1988) *Representation and Reality*, Cambridge, MA: MIT Press.(Putnam reconsiders functionalism, his early philosophy of mind, in the light of his views on meaning, and his critique of naturalism.)
Putnam, H. (1990) *Realism with a Human Face*, ed. J. Conant, Cambridge, MA: Harvard University Press.(A collection of essays by Putnam, selected and introduced by the editor. The essays in this volume are divided into three groups: metaphysics; ethics and aesthetics; studies in American philosophy. The rejection of the fact/value dichotomy is a central theme of this collection.)
Putnam, H. (1992) *Renewing Philosophy*, Cambridge, MA: Harvard University Press.(This book grew out of the Gifford Lectures, St Andrews 1990. It takes issue with scientism in several areas such as artificial intelligence and ethics, while maintaining the possibility of a cognitive relation to reality.)
Putnam, H. (1994) *Words and Life*, ed. J. Conant, Cambridge, MA: Harvard University Press.(A collection of essays by Putnam, selected and introduced by the editor. Some of the essays in this volume, such as ‘Rethinking Mathematical Necessity’ reflect Putnam’s growing attraction to the later Wittgenstein. Others discuss pragmatism, logical positivism, the philosophy of mind and the role of philosophy in our lives.)
Putnam, H. (1995) *Pragmatism*, Cambridge, MA, and Oxford: Blackwell.(First published in Italian as *Il Pragmatismo: Una Questione Aperta*, Rome, Bari: Gius Laterza & Figli Spa, 1992. Putnam’s version of pragmatism. Includes a bibliography.)

Pyrrho (*c*.365-*c*.275 BC)

The Greek philosopher Pyrrho of Elis gave his name first to the most influential version of ancient scepticism (Pyrrhonism), and later to scepticism as such (pyrrhonism). Like Socrates, he wrote nothing, despite which - or thanks to which - he too became one of the great figures of philosophy. Although he has vanished behind his own legend, he must have helped nurture that legend: his unique personality palpably exercised an unequalled fascination on his acquaintances, and through them, on many others. We possess, thanks especially to Sextus Empiricus, extensive documentation of what can be called 'Neo-Pyrrhonian' scepticism, because from the time of Aenesidemus (first century BC) it invoked Pyrrho as its patron saint. But Pyrrho's own thought is hard to recover. The documentary evidence for him is mainly anecdotal, and the principal doxography is more or less directly dependent on his leading disciple Timon of Phlius, who managed to present himself as Pyrrho's mere 'spokesman', but who was in fact perhaps rather more than that. The main question, which is still unanswered, is whether Pyrrho was primarily or even solely a moralist, the champion of an ethical outlook based on indifference and insensibility, or whether he had already explicitly set up the weaponry of the sceptical critique of knowledge which underlies the epistemological watchword 'suspension of judgment'.

1 Life

According to Diogenes Laertius (IX 61-70), who is following a life of Pyrrho written around 225 BC by Antigonus of Carystus, Pyrrho had been an obscure painter before his studies, which were first with Bryson (probably the Megarian philosopher of that name), then with Anaxarchus. Anaxarchus was a companion to Alexander the Great on his Asian campaign, and brought Pyrrho along too. Alexander's biographers speak quite often of Anaxarchus, but never of Pyrrho. On his return to Greece, Pyrrho lived in the countryside near Elis, surrounded by a group of admirers, but hardly seeming a head of school.

The numerous anecdotes about him reveal a split between two concurrent images. On the one hand we hear of Pyrrho as an eccentric: indifferent towards himself as towards others, he leaves himself entirely unprotected, taking account neither of sensations nor of the beliefs which guide practical life (fr. 6). He behaves as a fakir (fr. 16) who recalls his encounters with the 'gymnosophists' or 'naked sages' of India (frs 1A, 10). He thus personifies a 'rustic' kind of scepticism, which subjects to 'suspension of judgment' not only learned doctrines but also beliefs found in ordinary life.

A second image, endorsed by Aenesidemus, is of a Pyrrho who suspends judgment when philosophizing but does not lack foresight in his practical life (fr.7). He lives in a manner which is modest, peaceful and relatively conformist (fr. 14), along with his sister and his farmyard animals, highly esteemed by his fellow citizens (fr. 11). He thus stands for an 'urbane' scepticism, which outlaws all doctrinal assertions but leaves intact the instinctive beliefs of everyday life.

This duality no doubt nurtured the debate as to what was the Pyrrhonists' chief good (*telos*) (Diogenes Laertius IX 108): insensibility (*apatheia*) according to some, gentleness (*praotēs*) according to others. It is possible, moreover, that both the 'rustic' and the 'urbane' image had their roots in the complexity of one and the same personality, as illustrated by some anecdotes. For example, the story goes that Pyrrho once fled from a vicious dog, and, reproached for violating his own principles of indifference, replied 'It is difficult to strip yourself completely of being human' (fr. 15A-B). We should take it that his ambition really was to escape the human condition, but that he knew himself incapable of unfailingly achieving this.

2 The legends

More by his personality than by his ideas, no doubt, Pyrrho created a sensation: he gave the impression of having found a new way of being happy. A disciple, Timon, asks him the secret of his superhuman serenity (frs 60-1). Another, Nausiphanes, reported that one of his own pupils used to question him eagerly about Pyrrho's conduct (fr. 28); the pupil's name was Epicurus (§1). When Cicero speaks of Pyrrho, he never describes him as a sceptical critic of knowledge (despite having the opportunity to do so), but always as an absurdly rigorous moralist (frs 69A-M), even more radical than the extremist Stoics Ariston of Chios (§2) and Herillus. Pyrrho must, nevertheless, have cared as little about the difference between knowledge and ignorance as about anything else;

Timon contrasts his tranquil lack of curiosity to 'the empty wisdom of the sophists' (fr. 60). Later, his condemnation of the branches of knowledge as useless could be presented as a way of condemning knowledge itself as impossible.

His chronological position inevitably favoured this metamorphosis. Aristotle's junior by twenty years, Pyrrho was still in his forties when Aristotle and his former pupil Alexander the Great both died (322 and 323 BC), that is, at the start of the Hellenistic age. He was a generation older than Epicurus and the Stoic Zeno of Citium, the founders of the two great new schools of this era (see Epicureanism; Stoicism). And he was two generations older than Arcesilaus, who restored scepticism to the Platonic Academy. He was therefore perfectly placed to appear a pivotal thinker in the eyes of posterity. Just before him, Aristotle seemed to have brought to completion an era of intellectual audacity, in which thinkers had vied in cognitive ambitions without necessarily considering their multiple disagreements a fatal drawback; when they had discussed knowledge, they had tended to suppose that its existence and possibility went without saying, and instead set themselves the task of analysing its nature, its tools and its methods. After Pyrrho, on the other hand, and throughout Hellenistic philosophy, there was a concern as to whether we really do have cognitive access to the world: the new schools placed the problem of the 'criterion of truth' at the head of their agenda, and their solutions to it marked the crucial distinction between dogmatists and sceptics (Hellenistic philosophy). It looks as if, in the intervening time, a radical new challenge to the very possibility of knowledge had been thrown down. When the author of this challenge is sought, Pyrrho emerges as the perfect candidate. One might even speak of a duel fought between Aristotle and Pyrrho. When Aristotle (*Metaphysics* IV) speaks of the manner of speech, thought and action to which those who deny the law of non-contradiction are condemned, he uses expressions which recur in the reports of Pyrrho's behaviour and in the formulas which he recommends using. It is as if Pyrrho had found a way to show that one could perfectly well live, speak and think in just the way Aristotle had said one could not (unless these coincidences were a later imposition designed to make Pyrrho look like the hero of an unprecedented philosophical rebellion.)

To correct this exaggerated portrayal, it is enough to notice that Pyrrho's contemporaries and successors, even the most enthusiastic of them, do not present him as an innovative theorist. Timon, despite doing more than anyone else to place him on a pedestal, nevertheless does not make him stand altogether alone: it is he who first assembles that gallery of ancestors (the Eleatics, Democritus, Protagoras and, above all, Xenophanes) which is thereafter associated with Pyrrho by the doxographers and authors of 'successions' (see Doxography).

Much later, from Aenesidemus to Sextus Empiricus, Pyrrho's name reappeared in the titles of sceptical works (*Pyrrhonian Discourses*, *Pyrrhonian Sketches*) as emblematic of a scepticism senior to that of Arcesilaus and altogether uncontaminated by the New Academy: after long neglect, it became a prestigious flag to wave. In this late era little was still known about Pyrrho. It was in any case sensible for a Pyrrhonist to disavow that name, as did Theodosius (second century AD), who remarked that 'given that the movement of someone else's thought is undiscoverable, we will never know what Pyrrho's mental disposition was; and not knowing that, we could not label ourselves Pyrrhonists' (fr. 41). It is notable that Sextus' only response to this objection is the mild one that scepticism can be called Pyrrhonism 'owing to the fact that Pyrrho seems to us to have devoted himself to the activity of sceptical inquiry (*skepsis*) more solidly and manifestly than his predecessors' (fr. 40) (see Pyrrhonism).

One may wonder, in the circumstances, whether Pyrrho's posthumous fate does not result from a sort of collage: the overwhelming originality of his ethical message, immediately recognized and celebrated, seemed to demand as its complement a radical critique of epistemology. This latter may have been bestowed on him retrospectively, in the way that philosophers often get saddled with the real or imagined consequences, or premises, of their ideas.

3 The key testimony

It would clearly be presumptuous, and would perhaps make little sense, to pretend to reconstitute the 'real' Pyrrho behind, or in front of, his multiple reflections. Reale (1981) has distinguished no fewer than eight defensible types of interpretation of Pyrrho's philosophy. Some separate him only narrowly, others widely, from the epistemological and phenomenalist scepticism of the neo-Pyrrhonists. For some he is above all an ascetic proponent of indifference; for others a nihilistic theorist of pure appearance and radical critic of all ontology. Such diversity is all the more surprising given the existence of a text (fr. 53) universally considered the centrepiece of Pyrrho's doxography, and respectable as much for its pedigree (it is cited by Eusebius from the late first century BC philosopher Aristocles, who himself drew its substance, if not its letter, from Timon) as for its content: an

overview of Pyrrho’s philosophical project. Clear and instructive in appearance, at a first reading this text seems to attest that Pyrrhonism does indeed have a fundamentally ethical goal, and that there are two closely linked means to its achievement: practical indifference and abstention from judgment, the latter going hand in hand with a complete disqualification of the ordinary instruments of knowledge. But the articulation of these different elements raises difficulties; and by scrutiny of the text we may be able to perform a task widely judged by interpreters to be impossible or useless: to separate Pyrrho’s original message from Timon’s own contribution.

Anyone who is on the verge of being happy, says Timon, should consider three questions: what the nature of things is, how we should be disposed towards them, and what benefit those who adopt this attitude will derive from it. The sequence of these three questions is itself puzzling: no latter-day sceptic would inquire about ‘the nature of things’ before asking himself whether we can know it. Pyrrho nevertheless does ask this; and he replies - in the one phrase of the text which Timon expressly attributes to him - that ‘things are entirely undifferentiated, undetermined and undecided’. This no doubt means that it is we who introduce the differences which appear to us to distinguish them (fr. 64). But what differences? He might mean all differences, including those of colour and so on as much as those between values. Or he might mean only these latter. Another summary (fr. 1A) has Pyrrho saying ‘that nothing is fair or foul, just or unjust, and that likewise in every case nothing is really (this or that), and that it is by custom and habit that people do everything they do; for nothing is any more this than that’. These generalizations seem restricted to the sphere of practical ethics.

Aristocles’ summary, after characterizing ‘things’ as ‘undifferentiated’, strangely adds that ‘for this reason, our sensations and beliefs are neither true nor false’. Here again, a latter-day sceptic would say otherwise, indeed the reverse: that our sensations and beliefs are untrustworthy, and that therefore ‘things’ are in their nature undifferentiated. Some have even emended the text to make it say this. However, once we notice that the grammar of the text attributes this bizarre inference to Timon, not to Pyrrho himself, we may prefer not to emend it, but to see in its very incongruity the traces of Timon’s own intervention, a somewhat clumsy epistemological graft onto the original Pyrrhonian trunk.

The second point on the Pyrrhonian agenda admittedly does not help much with testing this hypothesis. In the face of undifferentiated ‘things’, the attitude that we should take is that of respecting their non-differentiation: we must be ‘unopinionated, uninclined, undisturbed’ either positively or negatively towards anything. These expressions can be interpreted as describing a refusal to affirm, just as much as a refusal to choose. And the same equivocation between theory and practice persists in the description of the discourse that goes with this behaviour: it is appropriate to say, of each thing, that ‘it is no more (this or that) than it is not it’, or again (no doubt with the implication ‘if it is necessary at all costs to say something positive or negative’) that it is appropriate immediately to negate our assertion, saying that ‘it is (this or that) and at the same time that it is not it’, or that ‘it neither is (this or that) nor is not it’. These expressions are remarkable; but they do not make it clear whether ‘this or that’ covers all possible predicates, or only those which, like ‘desirable’ and ‘undesirable’, concern the sphere of action.

One who is ‘on the verge of being happy’ must last consider - and this is the final phase of the Pyrrhonian programme - ‘what will happen to those who are disposed thus’ (that is, ‘without opinions’ and so on, as already defined). Whoever is reformed by Pyrrhonian training, says Timon, will achieve first *aphasia* (not in its modern sense of mutism, but a sort of non-assertive, non-committal use of language), then *ataraxia* (complete lack of disturbance, perfect unworriedness). It is worth noticing that the attainment of this benefit is here described as predictable. In later Pyrrhonism (Sextus Empiricus, *Outlines of Pyrrhonism* I 28-9), and already in Timon (Diogenes Laertius IX 107), there was to be on the contrary an insistence that *ataraxia* results unexpectedly, by a happy chance, from suspension of judgment. Might this difference not be the result of the epistemological graft hypothesized above? That *ataraxia* should result from practical indifference makes sense: freed of all preferences, we will no longer undergo the feelings which upset us. But that *ataraxia* should result from suspension of judgment makes less sense: the renunciation of all certainty might seem, on the contrary, to condemn us to everlasting anxiety. The appeal to ‘happy chance’, an innovation on the rational planning offered by Pyrrho’s programme, may therefore reflect the new complexity introduced into the sceptic’s itinerary by the epistemological detour. If this analysis of the key testimony in Aristocles is correct, we are entitled to say, even more firmly than before, that Pyrrho was not the first of the Pyrrhonists.

Pyrrhonism

Pyrrhonism was the name given by the Greeks to one particular brand of scepticism, that identified (albeit tenuously) with Pyrrho of Elis, who was said (by his disciple Timon of Phlius) to have declared that everything was indeterminable and accordingly to have suspended judgment about the reality of things - in particular whether they were really good or bad. After Timon's death Pyrrhonism lapsed, until revived by Aenesidemus. Aenesidemus held that it was inadmissible either to affirm or to deny that anything was really the case, and in particular to hold, with the Academic sceptics, that certain things really were inapprehensible. Instead, the Sceptic (the capital letter denotes the Pyrrhonists, who adopted the term, literally 'inquirer', as one of the designations for their school) should only allow that things were no more the case than not, or only so under certain circumstances and not under others. Aenesidemean Scepticism took the form of emphasizing the disagreement among both lay people and theoreticians as to the nature of things, and the fact that things appear differently under different circumstances (the various ways of doing this were systematized into the Ten Modes of Scepticism); the result was meant to be suspension of judgment about such matters, which would in turn lead to tranquillity of mind. Thus 'Scepticism' denotes a particular philosophical position, not simply, as in modern usage, that of any philosopher inclined towards doubt. Later Pyrrhonists, notably Agrippa, refined the Sceptical method and concentrated on undermining the dogmatic (that is, anti-Sceptical) notion of the criterion - there is no principled way to settle such disputes without resorting to mere assertion, infinite regress or circularity. We owe to Sextus Empiricus our most complete account of Pyrrhonian argument and the clearest exposition of the Pyrrhonian attitude. Faced with endemic dispute, Sceptics reserve judgment; but this does not render life impossible for them, since they will still react to the way things appear to be, although without believing in any strong sense that things really are as they seem. Furthermore, when Pyrrhonians describe their affective states, they do so undogmatically - and the Sceptical slogans ('I determine nothing', 'nothing is apprehended', and so on) are to be understood in a similar way, as merely reporting a state of mind and not expressing a commitment. Thus the slogans apply to themselves, and like cathartic drugs are themselves purged along with the noxious humour of dogmatism.

1 History

Greek scepticism is inextricably associated with the name of Pyrrho; the ancients themselves dubbed the most enduring and interesting form of scepticism of their times 'Pyrrhonism' after its eponymous origin. Yet surprisingly little is known about Pyrrho the man, and it is possible that he was not even a Sceptic (in the strict sense of the term) at all (see Pyrrho §3). He lived from *c*.365 to *c*.275 BC, and his name became a byword for philosophical detachment from the ordinary concerns of life. Legend has it that his friends had to prevent him from walking over cliffs and under passing traffic; this and other amusing if apocryphal stories are recorded in the biography by Diogenes Laertius. He wrote nothing, and most of what we know of him derives from the writings of his disciple and amanuensis Timon. According to Timon, Pyrrho held that to be happy we must confront three questions: How are things by nature? What attitude should we adopt towards them? What will be the outcome for those who have this attitude? He answered that all things were equally indifferent, unmeasurable and undecidable, and that our perceptions told us neither truths nor falsehoods about the way things really are. The upshot of this is that we should be free of all opinion and commitment. The proper attitude to anything is to suppose that it no more (*ou mallon*) is the case than not. As a result we should simply acquiesce in the way things appear without having any strong beliefs concerning the way they actually are.

These remained the characteristic attitudes of Pyrrhonism throughout its history. However, original though Pyrrho undoubtedly was (even if the tradition suggests that he learned philosophical detachment from Indian philosophers while following Alexander the Great's expedition with Anaxarchus), his scepticism was not entirely without precedent. Ever since Xenophanes (§5), Greek thinkers had puzzled over the nature and scope of human knowledge, and whether it was genuinely possible. Some fragments of Democritus in particular suggest a cautious attitude to the possibility of human understanding, and Democritus (§3) employed the formula 'no more' on occasion to indicate a sceptical refusal to commit himself one way or the other on some question. Moreover, Aristotle is clearly aware of sceptical challenges to our ability to rely upon our senses (*Metaphysics* IV 4-5), although he dismisses them as mere captiousness (it is possible that he knew of Pyrrho's scepticism).

There is no hint of a concerted and systematic attempt to question our justification for belief in the natures of

things before Pyrrho, however. Indeed Pyrrho himself may not have mounted a general assault on the reliability of the senses (although Timon evidently did), so much as a limited attack on our pretensions to ethical knowledge, or, more generally, knowledge of matters of value; in later antiquity, Pyrrho's name was certainly associated primarily with ethical (in the broad Greek sense) issues; and it was principally as a role model for a certain way of life, one in which tranquillity is to be achieved by a refusal to allow oneself strong commitments of any kind, that Pyrrho's fame was maintained in later antiquity.

After Timon's death Pyrrhonism as such died out, although the New Academy of Arcesilaus and Carneades kept alive the sceptical tradition for the next two centuries, in the course of their long and tortuous epistemological conflict with the Stoics. The latter held that empirical certainty was attainable, on the basis of 'apprehensive' impressions whose clarity and distinctness were assurances of their truth (see Stoicism §12); the Academic sceptics countered by arguing that there was no true impression that was such that there could not be a false one indistinguishable from it in all internal characteristics: consequently, there was no criterion by which to judge whether or not an impression was indeed apprehensive.

By the first century BC both sides had so modified their positions as a result of the dialectical sparring that it was becoming increasingly difficult to tell the two schools apart, so much so that when (a little after 90 BC) Philo of Larissa relaxed Academic strictures against the possibility of knowledge, Antiochus seceded from the Academy altogether and adopted a position very similar to the Stoics. Reacting against this dilution of the pure sceptical spirit, Aenesidemus re-founded Pyrrhonism. Aenesidemus' works are all lost, but a ninth-century summary of his eight-volume *Pyrrhonian Discourses* by Photius survives, which allows us to recreate something of its flavour. The target of his attack was the belief that apprehension, or secure knowledge of the nature of things, was ever attainable. Nobody really knows how things are, yet everybody but the Pyrrhonists claims to do so, wasting their time in futile, dogmatic bickering. Indeed, from this time on 'dogmatic' as applied to a philosopher or philosophical view, carries the connotation 'non-Sceptical': a dogmatist is anyone who professes belief in *dogmata*; and a *dogma* is, according to Sextus Empiricus, an 'assent to one of the non-evident objects of scientific inquiry' (*Outlines of Pyrrhonism* I 13). Such matters are 'non-evident' precisely because they go beyond what is strictly contained in the appearances, the *phainomena*, themselves.

Aenesidemus apparently held that there was as a matter of fact no apprehension of things. He sought to distinguish this position from that of the sceptical Academy on the grounds that they (according to him) were prepared actually to affirm certain things absolutely, notably that apprehension was impossible; by contrast Aenesidemus' position is provisional - he has no apprehension *now*, but apprehension might yet be possible. Even so, the appropriate Pyrrhonian attitude to things is to say that they are no more so than not so, or sometimes so and sometimes not so, or so for some people and not for others. Thus Aenesidemus appears to allow a form of relativism. Relativism and Pyrrhonism are incompatible however: relativism positively asserts that there is no genuine fact of the matter, a relativist in ethics appealing to the facts of cultural divergence (as indeed will the Pyrrhonist); but while the relativist will conclude that there is no such thing as an objective good, or right and wrong, the Pyrrhonist will simply infer that we do not know whether any things are genuinely good, and, if any, which. The Pyrrhonist makes no metaphysical claims about the ontological status of such 'objects'; and hence when Aenesidemus says that some things are one way for some people and otherwise for others, he is not asserting that things *really* are that way - this is simply a report of how things seem to be.

2 The Ten Modes of Scepticism

Fundamental to the Pyrrhonists' method was the collection of cases in which things seem different under different circumstances. They appear differently to people as opposed to animals (muddy water appeals to pigs but not to us: Sextus Empiricus, *Outlines of Pyrrhonism* I 56), to different groups of people ('Indians enjoy different things from us': I 80), to different sense-modalities ('Paintings seem bumpy to vision, smooth to touch': I 92), and to the same sense-modality on different occasions ('Honey seems sweet to the healthy, bitter to the jaundiced': I 101). These are examples of the first four of the Ten Modes of Scepticism. Many of the examples retailed in the modes are Greek commonplaces, deriving from much earlier times (some may be found in Aristotle; and one of Sextus' examples of the first mode - that sea water is poisonous to humans but nourishing to fish - is drawn from Heraclitus (§3)). What is important is the systematic way in which they are collected, and the use to which they are put. Aenesidemus may well have been the first to collect the material and organize it into ten separate modes

(although this is controversial); in any event, a generation or so later, in the time of Philo of Alexandria (one of our major sources for the modes; see Philo of Alexandria §1), they were firmly associated with Pyrrhonian Scepticism.

A mode (*tropos*) in this sense is a general pattern of argument, for which any number of specific instances may be found. The basic structure of all of the modes is simple and lucid. Sextus describes Pyrrhonism as a 'capacity for opposition' (*Outlines of Pyrrhonism* I 8): arguments are opposed to arguments, appearances to appearances, and arguments to appearances (I 8-9, 31-3). Whenever the issue goes beyond how things seem to particular individuals (that is, the way things *really* are), there is, the Pyrrhonists note, an 'undecidable disagreement' about the matter. Moreover, that dispute is undecidable because of the unavailability of any generally accepted means of resolving it, any criterion in the technical Greek sense (see §5). And in default of that, the Pyrrhonist urges, there is no reason to prefer one of the appearances to another, and hence we should not commit ourselves to any of them: we should suspend judgment about them (see §4). All the modes, then, share the following basic form:

(1) x appears F relative to a
(2) x appears F^* relative to b
(3) at most one of 'x is F' and 'x is F^*' can be (objectively) true
(4) no uncontroversial decision procedure tells decisively either for 'x is F' or for 'x is F^*' so
(5) we should suspend judgment as to what x is really like.

The range of x (for example, 'sea water' in the Heraclitus case) is broad and varies from mode to mode, as do the predicates covered by the variables F and F^*; what substitutes for a and b is determined by the particular nature of each mode (thus in the first mode 'a' will be humans, 'b' other animals, fish for example; in the second a and b will be different individuals or groups of humans; and so on for the other modes). The substituends for F and F^* must be incompatible predicates (for example, 'poisonous' and 'nourishing'), and since they are incompatible, (3) follows trivially. Then, on the supposition that (4) can be made good, (5) follows on reasonable assumptions about rationality.

Sextus Empiricus, our main source for the modes, spends most of his time collecting examples of (1) and (2) for each of his different modes. The first four he labels 'modes from the judger': that is, the various types of opposition are to do with variations in the individuals observing them. Modes 'from both judger and judged' include the fifth, which notes that the appearance of things varies according to the distance and standpoint from which they are viewed (this is the source of the hardy philosophical perennial that a straight oar looks bent in water: *Outlines of Pyrrhonism* I 119), and the ninth notes that our appreciation of things differs according to how familiar we are with them (naked bodies become unexciting after a while: I 142). The seventh and tenth modes are labelled 'from the thing judged' (although in the latter case it is hard to see why); the seventh is to do with supposed variations in the constitutions of things which are observed under various conditions (thus the filings of black horn look white: I 129), and it is very hard to see what Sceptical leverage such considerations might have; the tenth is the mode 'mainly concerned with ethics, having to do with ways of life, habits, laws, mythical beliefs and dogmatic suppositions' (I 145), in which Sextus collects with evident enthusiasm examples of cultural diversity ('Indians copulate in public': I 143; 'Persians marry their mothers': I 152). These examples are multiplied in a later, more general treatment of ethics (I 3 168-238).

The tenth mode in particular emphasizes an important issue. The proper Pyrrhonian conclusion from the facts of ethical diversity is, according to Sextus at least, that we cannot know whether or not anything is good or bad by nature (I 163, III 235); yet the ethical relativist will equally appeal to precisely the same examples in order to ground the different and incompatible conclusion that *nothing* is good or bad *by nature*: there simply are no fundamental facts about value. The Pyrrhonist avoids this move because it too is a species of dogmatism, albeit negative in form. Different people disagree; and that is all there is to it. For all we know there may be actual absolute values. The relativist, negative conclusion is just as unwarranted as its positive dogmatic opponent. Just as the Pyrrhonists will not say that everything is inapprehensible (although allowing that nothing actually seems to be apprehended: see §1), neither will they absolutely deny the existence of objective values.

Similarly, when propounding the eighth mode, the 'mode of relativity', the Pyrrhonist only affirms that everything *appears* to be relative (I 135), although (as Sextus notes elsewhere: I 39), relativity is in fact at the core of all of the modes' procedures (as (1) and (2) above make clear). Thus there is no second-order commitment to the *truth* of the claim that everything is relative; even that is a matter of appearances.

3 The Sceptical slogans

This is the core of the Pyrrhonian position. Pyrrhonists liked to sum up their philosophy in pithy slogans (such as 'I determine nothing': *Outlines of Pyrrhonism* I 197): but this merely means 'I am now so affected as neither to affirm nor deny dogmatically any of the subjects under investigation'. Equally, ' Everything is inapprehensible' only means 'All the non-evident subjects of dogmatic inquiry which I have investigated seem to me inapprehensible' (I 200), and similar caveats apply to 'to each argument an equal argument is opposed' (I 202-3), and *ou mallon*: ' the phrase "no more this than that" expresses our affection, by which we end up in equipoise because of the equal strength of opposing matters' (I 120). The end result is suspension of judgment, or *epochē* (stage (5) see §2 above); even then, the Pyrrhonist is careful to say only that matters *appear* equally balanced (I 196), while Sceptical *aphasia*, or non-assertion, is 'an affection of ours because of which we neither affirm nor deny anything' (I 192); moreover, its scope covers only 'what is said dogmatically in regard to things non-evident, since we yield to those things which move us affectively and force us necessarily to assent' (I 193).

Pyrrhonists, then, can say how things seem to be to them, and report the way they are affected; they live their lives according to those appearances, but 'undogmatically', that is, without any commitment to their underlying truth. Furthermore, the 'Sceptical expressions' such as 'I determine nothing' apply to themselves; for the Pyrrhonist, unlike some varieties of relativist, there is no privileged meta-language in which unalloyed second-order truths can be expressed: it is Scepticism all the way down. Thus Pyrrhonism manages to avoid being (at least in any damaging sense) self-refuting, precisely, if paradoxically, because the Sceptical slogans apply to themselves: Sextus compares them to purgative drugs which eliminate themselves along with the 'noxious humours' which are their object (I 206).

4 The criterion, signs and proof

The Ten Modes of Scepticism are ascribed by Sextus to 'the older Sceptics' (*Outlines of Pyrrhonism* I 36). By contrast, a set of five modes, more general in scope, is attributed by him to 'the more recent Sceptics' (I 164). Although in Sextus' presentation each of the ten modes concludes with suspension of judgment, the arguments by which that is supposed to commend itself are not spelled out in detail; the final steps of the basic schema outlined in §2 still require elucidation.

The modes of Agrippa organize the Sceptical material rather differently: two modes emphasize, in general terms, disagreement and the relativity of appearances, while the other three aver that any attempt to resolve the dispute will result either in mere assertion, infinite regress or circularity (see Agrippa). These three formal modes are in evidence throughout Sextus' presentation of Pyrrhonian argument; and they ultimately give the reasons why oppositions of the sort collected by the ten modes result in *epochē*. But, as Sextus was well aware, this is tricky, since elsewhere Pyrrhonists cast doubt on the validity of argument itself. If proof is doubtful, why imagine that (1)-(4) should entail (5)? Crucially, Sextus nowhere relies on the success of that entailment. Rather, perfectly consistently, he simply describes his own affective states. Persistent disputes of the sort gathered by the ten modes, and the persistent appearance that everything is relative, cause him to suspend judgment about things; but that too is simply an appearance, albeit an appearance of his own mental states, which he is at perfect liberty (non-dogmatically) to express.

Moreover, Pyrrhonian arguments are dialectical, directed against the various schools of dogmatists. If dogmatists believe in such things as proof, then they must, by their own lights, accept the Sceptics' arguments (if they are valid). The Sceptics, by contrast, are not obliged to accept them, and do not do so (although they do not reject them either); but since they do not suffer from dogmatic belief they have no need of them. The bulk of book II of *Outlines of Pyrrhonism* is taken up with such issues - and Sextus opens the argument with a vigorous defence of the salubrity of the Sceptic's procedure of investigating dogmatic doctrines on their own terms (II 1-12): the Sceptic can understand the content of the dogmatist's claims without being committed to it, and can thus point out what should (to the dogmatist) appear to be inconsistencies; and if there are such apparent inconsistencies, dogmatists themselves should abandon their own positions. All of the argument here concerns the criterion.

A criterion is, literally, something that judges: a touchstone. Criteria are standardly, in Hellenistic philosophy and after, divided into criteria of truth (means of judging true from false propositions) and criteria of action (ways to decide how best to behave). The Academics, in their battle with the Stoics (see §1), had denied the existence of the

former, while allowing that the latter were still available. Sextus seeks to cast doubt on all of the former, by the standard Pyrrhonian means of contrasting what differing dogmatic schools (primarily the Stoics and the Epicureans) had to say about the issue, as well as by pointing to internal difficulties in their several accounts. Thus Academic arguments are retailed against the Stoic criterion of the 'apprehensive impression', but not in order to show positively that there is no such thing (II 79).

Perhaps most characteristic is the claim that, since the existence of a criterion is itself a matter of dispute, it too requires a criterion to resolve it: but none is available, except on pain of infinite regress or circularity (II 20, 34-5). Given ubiquitous dispute, we might look for majority agreement, but that is hardly to be found, and even if it were would be no guarantee of the truth (you can fool almost all of the people some of the time, as the Stoics themselves allowed): Sextus employed similar considerations in discussion of the second of the ten modes (I 87-9); and elsewhere he refuses even to allow that universal agreement on an assertion is enough to show that it is true, since present consensus is no guarantee that future disagreements will not crop up (I 33-4).

Here an earlier issue resurfaces. What is wrong with adopting the Protagorean position that everyone is judge and jury in their own case? (See Protagoras §3.) Exactly that, Sextus thinks: criteria should be independent. But why? Once again it is vital to place Sextus' argumentation in its dialectical context. Again and again, he will claim that some dispute, or opposition among arguments, or disagreement about appearances, is sufficient to induce *epochē* 'concerning how things are absolutely and in their real nature' (for example, *Outlines of Pyrrhonism* I 135). He is here relying upon what had become a commonplace of non-Sceptical metaphysics, namely that if something possesses a property essentially, it must do so under all circumstances and in all conditions; but surely the irremediable variability of appearances casts doubt upon our ability to infer to such properties; and if that commonplace is to be given a strong construal, the mere fact that nothing appears the same under all circumstances is enough to show that none of its apparent properties is, in this sense, real. Once more, that conclusion is presented as being something the dogmatist is forced, willy-nilly, to accept; the Pyrrhonist, of course, simply suspends judgment.

All of this is powerful and pointed; and it is backed up by the Sceptical attack on signs in general and proofs in particular. In the latter case, Sextus seeks to show that, on their own account, dogmatic conceptions of proof are self-stultifying (his principal target here is Stoic logic, his method to show that, on the Stoics' own account of the truth-conditions for the conditional, every proof will contain a redundant conditional premise; and yet redundancy is, on the Stoics' own account, invalidating) (II 159). More generally, Sextus argues that the dogmatists' 'indicative sign' cannot fulfil its supposed function (Sextus is however, perfectly happy to allow the existence of commemorative signs, whereby one evident phenomenon serves as a sign of some other, temporarily non-evident, phenomenon, on the basis of past experience). An indicative sign was defined as 'an antecedent in a sound conditional which serves to reveal the consequent' (II 101), where the consequent is something by nature non-evident (as sweating, in the dogmatists' stock example, is supposed to reveal the existence of invisible pores in the skin). But, the Sceptics urge, if what is signified is such as never to be evident, how can we know that it has been so revealed?

5 Cause and explanation: Sceptical physics

Dogmatists may reply that perhaps the phenomena are such that there is only one possible set of underlying circumstances which could account for them (as is alleged in the sweating-pores case). The atomists held that it was only on the assumption that the world was fundamentally composed of atoms and the void that evident facts of experience (such as the existence of motion) could be explained (see Atomism, Ancient; Democritus §2; Epicureanism §2): perhaps such quasi-transcendental inferences really can take us indubitably to the heart of things. But the Sceptics simply respond that there is no reason to think that there are any such valid inferences - after all, most physical theorists reject the atomist inference from motion to the void.

Such considerations formed the core of a set of eight modes against the aetiologists, attributed to Aenesidemus. These modes consist of a set of general Sceptical reflections on the limitations of explanation: 'The first is that according to which…aetiology in general, being concerned with non-evident things, has no agreed confirmation'; 'The second shows that frequently when there are many ways of assigning an explanation to what is being investigated, some of them account for it one way only' (*Outlines of Pyrrhonism* I 181). That is, there is no general way in which we can determine the truth (if any) of non-evident matters, since they tend to be susceptible

of different interpretations. The fourth mode further notes that dogmatists assume, unfoundedly, that the micro-mechanisms to which they 'infer' will be, in general, much like their phenomenal counterparts; furthermore, all theorists are inclined to overlook awkward recalcitrant facts, as well as contradicting the evidence and sometimes themselves, and in general begging the question in favour of their own position.

Aenesidemus' eight modes attack dogmatic scientific methodology. Elsewhere (III 13-30) Sextus retails more general arguments designed to cast doubt on the coherence of the notions of cause and explanation (some of these arguments mirror those against signs from the previous book). Causes must either precede their effects, or be concurrent with them, or succeed them. The last option is absurd; and cause and effect are relative, so one cannot precede the other; yet a cause is supposed to be productive of something, and hence must precede what it is productive of. This is just one of a battery of arguments Sextus rehearses here and elsewhere (for example, *Against the Professors* IX 210-51): he also urges that causes should invariably bring about their effects, and yet everything dogmatists refer to as a cause is defeasible; thus not even fire can really be of a nature to burn since it will not burn everything under all circumstances). Sextus then uses the apparent results of the attack on causation to undermine the rest of dogmatic physics: body is that which can act and be acted upon (*Outlines of Pyrrhonism* III 38), so if there is no agency, there is no body either (and out with it go a host of related notions such as limit, surface and solidity); and equally doomed are the nest of concepts relating to change (motion, increase, rest, and so on), while if these go, so do the ideas of addition and subtraction, and with them arithmetic and the concepts of part and whole.

6 The Sceptical end

Most of Sextus' argument is devoted to attacking dogmatic concepts, yet he never loses sight of the overall goal of the Pyrrhonian procedure of constructing a dispute - it is just that the vast majority of people (and not just dogmatic theorists) believe in the existence of bodies, motion, and so on, and consequently that arm of the disagreement needs little support. Thus, first appearances notwithstanding, all of this is consistent with the general aim of Pyrrhonism. None the less, the question remains: why bother? Why should Pyrrhonists concern themselves at such length with refuting dogmatists, not to mention the views of ordinary people? The latter case is in fact particularly pointed, since Sextus frequently says that he has no quarrel with ordinary views and that he sides with life. Why, then, try to argue that motion is non-existent? Furthermore, while Sextus will on occasion argue that not even fire is warm by nature, elsewhere he will contrast the case of fire with that of ethical values, saying that the latter would have to be like fire if they were to be natural properties (*Outlines of Pyrrhonism* III 179); surely that is simple inconsistency?

The answers to these questions are controversial, but the following account seems at least coherent. Sextus does not conceive of argument in the ordinary philosophical way as entailing (or at the very least rationally buttressing) conclusions. As seen in §5, he is perfectly happy to argue against argument. Rather arguments affect us in just the same way as phenomenal appearances do; and we may, non-dogmatically, report those effects. Thus, when confronted with an equally balanced pile of considerations on both sides of an issue, I do not *conclude* that it is *rational* to suspend judgment: rather *epochē* just happens to me. Furthermore, Sextus characterizes Sceptics as perpetual investigators: why should they need to go on investigating once they have attained *epochē*? The answer is precisely that *epochē* is not rationally inferred by argument: rather it is a state, and one that is in constant need of replenishment; moreover the Sceptic goes on investigating in response to the way things seem.

Sceptics of all stripes were greatly concerned to evade the charge that life without belief (at least dogmatic belief that things *really* are thus and so) was impossible, since belief is a necessary condition for action. Dogmatic belief, Sceptics claim, is not necessary: they act on the basis of their impressions, but with none of the commitment to the truth of those impressions characteristic of ordinary people's behaviour. This characterization of the Sceptic's attitude implies a position on a much discussed question (see Barnes 1982; Burnyeat 1983; Frede 1987): namely, just what is the scope of the *dogmata* the Sceptic rejects, an answer to which is of capital importance to the associated question of whether life can be lived without them. Are *dogmata* merely *scientific* beliefs, beliefs involving explicit commitment to theory (as *Outlines of Pyrrhonism* I 13 suggests, the line adopted by Frede)? Or are they any and every non-epistemic appearance (Burnyeat's view)? More probably what makes an appearance into a *dogma* is not its content, but one's attitude to it: any appearance can, on this view, be a *dogma*, but only if its recipient accepts it as *really* true. And such commitments are not prerequisites of all action.

The upshot of this rejection of *dogmata* is *epochē*: the payoff, Sextus claims, is tranquillity, *ataraxia*, the state of being untroubled by things in general (*Outlines of Pyrrhonism* I 25-30). Distress is caused by strong evaluations - get rid of those, and life will be simpler. Of course, as a Sceptic he cannot claim certainty for his prescription; this is just the way things seem to him. But he is moved by that appearance and his general philanthropy to offer these arguments to others as well. Indeed, in a famous passage at the very end of *Outlines of Pyrrhonism*, Sextus compares Sceptical arguments to drugs: their business is to effect a cure for morbid dogmatism. How they do so is no part of the Pyrrhonist's concern.

Pythagoras (*c*.570-*c*.497 BC)

Pythagoras of Samos was an early Greek sage and religious innovator. He taught the kinship of all life and the immortality and transmigration of the soul. Pythagoras founded a religious community of men and women in southern Italy that was also of considerable political influence. His followers, who became known as Pythagoreans, went beyond these essentially religious beliefs of the master to develop philosophical, mathematical, astronomical, and musical theories with which they tended to credit Pythagoras himself. The tradition established by Pythagoras weaves through much of Greek philosophy, leaving its mark particularly on the thought of Empedocles, Plato, and later Platonists.

1 Life and deeds

Pythagoras, son of Mnesarchus, was born on the island of Samos. For the first half of his life Pythagoras travelled widely, not only in Greece but supposedly also in Egypt, Phoenicia and Babylonia, where he is reputed to have acquired much of his knowledge and religious wisdom. Perhaps to escape the rule of Polycrates, the tyrant of Samos, he emigrated to Croton in southern Italy. His moral stature and eloquence gained him many adherents. With his followers, both men and women, Pythagoras practised a simple, communal life whose goal was to live in harmony with the divine. To that end he prescribed a regimen of purification that included dietary restrictions, periods of silence and contemplation, and other ascetic practices. In addition to the religious and monastic aspects of the Pythagorean society, we hear of Pythagorean political associations (*hetaireiai*) that played an important role in the public affairs of Croton and other southern Italian cities (it appears they initiated social reforms and supported aristocratic constitutions). After a time their dominance came to be resented and a ‘Pythagorean revolt’ ensued, in the course of which many Pythagoreans were killed or scattered abroad. Pythagoras himself, possibly as a result of this upheaval, moved to Metapontum where he died.

Already during his lifetime Pythagoras was regarded with near religious veneration. It is therefore not surprising that the stories told about him after his death should turn into hagiology and include many fantastic elements: that Pythagoras was the Hyperborean Apollo and had a golden thigh to prove it; that he was seen in two places at one time; that he could converse with animals and control natural phenomena. Pythagoras’ wonder-working clearly belongs to the realm of legend, although it reinforces the picture of him as a ‘shaman’. A more difficult matter is to establish what Pythagoras actually taught, since the oral and then the written traditions attribute to him not only miracles but also sophisticated mathematical and philosophical achievements. This habit of tracing all things back to the master, coupled with evidence of the quasi-religious avoidance of uttering his name, is typified in the expression common among Pythagoreans: ‘he himself said’ (*autos epha*; Latin *ipse dixit*). However, because Pythagoras wrote nothing and shrouded his lectures in secrecy, it is impossible to verify all that is ascribed to him. What remains certain is that he was a highly influential religious teacher whose main tenets dealt with the soul and the rites required for its purification and salvation. This made the Pythagorean movement especially popular in Magna Graecia, a fertile soil for mystery cults of all kinds. Pythagoras is also connected with certain ‘Orphic’ writings, since these share eschatological concerns similar to his oral teachings (see Orphism). For these reasons the following account will emphasize those doctrines that accord with Pythagoras’ reputation as an early Greek sage and religious innovator (for the philosophical and scientific theories traditionally associated with his name, see Pythagoreanism).

2 Teachings

Pythagoras believed that the world was animate and that the planets were gods. This view of the universe as living and divine was characteristic of early Greek thought (see Thales §2), but what appears unique with Pythagoras is the corollary he drew on an anthropological level: there is an element in human beings that is related to the universe and that, like the universe in which events recur in eternal cycles, is eternal. This divine, immortal element is the soul (see Psychē). With the death of the body the soul passes into another body, human or animal. An early witness to Pythagoras’ belief in transmigration (or *metempsychōsis*) is the poet-philosopher Xenophanes (§1), who satirizes him for claiming to recognize the soul of a friend when he heard the voice of a puppy that was being beaten. Pythagoras asserted of himself, as is typical of a religious figure who draws on personal experience, that he had once been the Homeric hero Euphorbus, and he exhorted his disciples to recall their own past lives.

The immortality of the soul underlies many of Pythagoras' practical teachings, for the soul, as the most important element within a person, required nurture to ensure not only equanimity in this life but also a better incarnation in the life to come. These ends could be achieved by bringing the soul into harmony with the divine, cosmic order (according to a disputed doxography, Pythagoras was the first to pronounce the world a *kosmos*, a term that in Greek combines the ideas of adornment, beauty and order). In so far, however, as the soul resided in a body, it needed to be freed from the turmoils and corrupting influences of the body. Hence Pythagoras preached a strict way of life that centred on purification (see Katharsis) and asceticism. Furthermore, he practised a form of musical therapy for both body and soul. He valued friendship highly as a means of promoting equality and concord; the love of friends was a specific instance of the universal sympathy existing in the cosmos.

The rules of Pythagoras found expression in short, pithy sayings known as *akousmata*, a term that implies oral transmission, or, more frequently, as *symbola*. The latter most likely functioned as secret passwords for Pythagorean initiates but, as the name suggests and their often esoteric and oracular nature prompted, they were also subjects for 'symbolic' interpretation. The *symbola* range from primitive religious taboos to simple moral precepts and various dietary prohibitions (abstinence from certain parts of animals and the famous ban on eating beans).

3 Legacy

Pythagoras, according to Plato (*Republic* X 600b), handed down to his followers a distinctive way of life (*bios*) 'they call Pythagorean to this day'. By Plato's day the Pythagorean life meant, besides purifications of the soul, inquiries in philosophy, mathematics, astronomy and music. Did Pythagoras bequeath these enterprises as well? Empedocles (§2), who was greatly influenced by Pythagoras, praised him as a man of surpassing knowledge, with a vast wealth of understanding, capable of all kinds of wise works. Heraclitus (§1), while agreeing that Pythagoras 'practised inquiry beyond all other men', saw the result as a peculiar wisdom consisting of polymathy and evil artifice. From both witnesses, however, Pythagoras emerges as a figure active in a wide variety of fields and therefore likely at least to have dabbled in those studies for which Pythagoreans were known in Plato's time. Still, the only sure legacy of Pythagoras is the immortality of the soul. Although this was primarily a religious belief, it carried philosophical import. By singling out the immortal soul as the essential element of life Pythagoras foreshadowed the Parmenidean/Platonic distinction between eternal being and changeable becoming and, in general, the dualism of mind and matter that informs so much of Western philosophy.

Pythagoreanism

Pythagoreanism refers to a Greek religious-philosophical movement that originated with Pythagoras in the sixth century BC. Although Pythagoreanism in its historical development embraced a wide range of interests in politics, mysticism, music, mathematics and astronomy, the common denominator remained a general adherence among Pythagoreans to the name of the founder and his religious beliefs. Pythagoras taught the immortality and transmigration of the soul (reincarnation) and recommended a way of life that through ascetic practices, dietary rules and ethical conduct promised to purify the soul and bring it into harmony with the surrounding universe. Thereby the soul would become godlike since Pythagoras believed that the cosmos, in view of its orderly and harmonious workings and structure, was divine. Pythagoreanism thus has from its beginnings a cosmological context that saw further evolution along mathematical lines in the succeeding centuries. Pythagorean philosophers, drawing on musical theories that may go back to Pythagoras, expressed the harmony of the universe in terms of numerical relations and possibly even claimed that things are numbers. Notwithstanding a certain confusion in Pythagorean number philosophy between abstract and concrete, Pythagoreanism represents a valid attempt, outstanding in early Greek philosophy, to explain the world by formal, structural principles. Overall, the combination of religious, philosophical and mathematical speculations that characterizes Pythagoreanism exercised a significant influence on Greek thinkers, notably on Plato and his immediate successors as well as those Platonic philosophers known as Neo-Pythagoreans and Neoplatonists.

1 History

In the second half of the sixth century BC, Pythagoras founded a community in the southern Italian city of Croton whose members were united by the belief in the transmigration of the soul, an ascetic way of life that centred on the purification of the soul, and a political outlook that aimed at social reform along aristocratic lines. Pythagorean associations (*hetaireiai*), which also formed in other cities of Magna Graecia, acquired considerable political authority, but their dominance eventually met with opposition, both during the lifetime of Pythagoras and later again about 450 BC. In the wake of these anti-Pythagorean movements the followers of Pythagoras were scattered throughout the Greek world, so that by the time of Plato there is little evidence of formal Pythagorean societies. Individual Pythagoreans, however, continued to be recognized, some by their distinctive lifestyle in matters of food, dress and purificatory practices, others by the additional pursuit of various philosophical, mathematical and musical theories with which they credited Pythagoras. Later tradition refers to these two types of Pythagoreans as ‘hearers’ (*akousmatikoi*) and ‘learners’ (*mathēmatikoi*). The distinction supposedly goes back to the original society in which some members were only fit to accept the oral teachings of Pythagoras without arguments and proofs, while those with more leisure and perhaps philosophical ability were further instructed in the rational foundations of the master’s teachings. Whatever differences there may have been between groups of Pythagoreans, and even among individual *mathēmatikoi*, all professed allegiance to Pythagoras.

From the time of Pythagoras to Plato there were several famous Pythagoreans - Hippasus, Philolaus and Archytas. Aristotle, in his extant works, speaks only generally of the Pythagoreans (‘some Pythagoreans say… ’); his special treatise on Pythagorean beliefs unfortunately no longer survives. In the third and second centuries BC we do not hear of philosophers who were known as or called themselves Pythagoreans, but interest in ‘Pythagoreanism’ continued, as is evidenced by the wealth of apocryphal writings in prose and verse on Pythagorean themes that mostly date from this period. The actual practice of Pythagoreanism experienced a revival in the Roman world from the first century BC to the first century AD; Latin writers such as Cicero, Ovid and Seneca testify to its popularity. In the first two centuries AD the theoretical side of Pythagoreanism marked certain philosophers to the extent that they may be called Neo-Pythagoreans (see Neo-Pythagoreanism) and these in turn influenced later Platonic philosophers (see Neoplatonism).

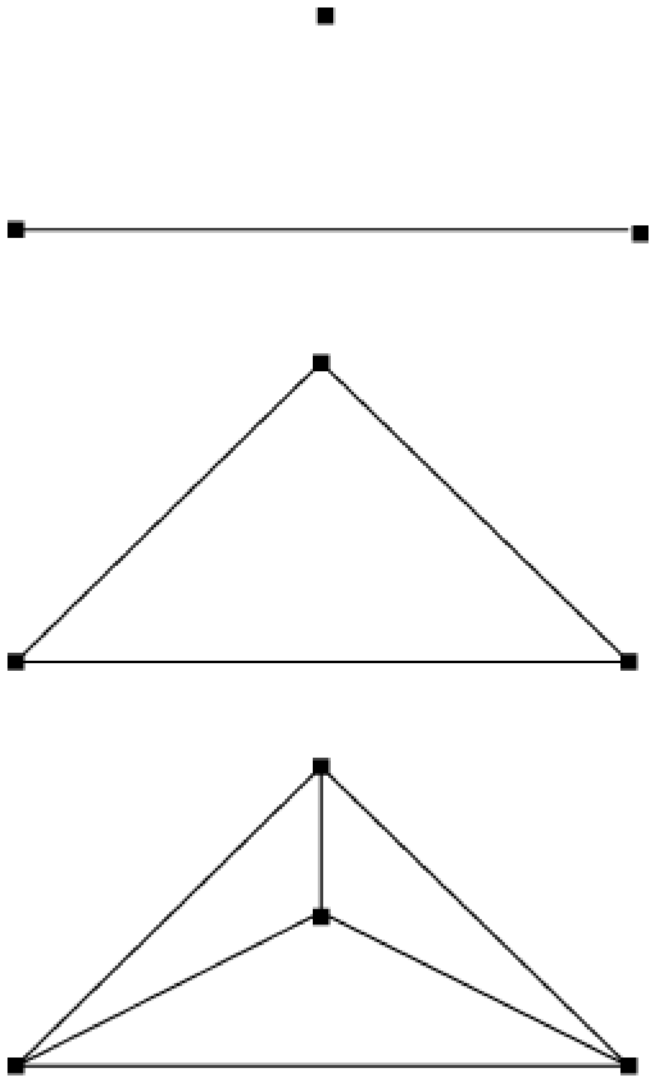
2 Music, mathematics, and cosmology

Plato says of the true philosopher, whose mind is on the higher realities (that is, the Platonic Forms):

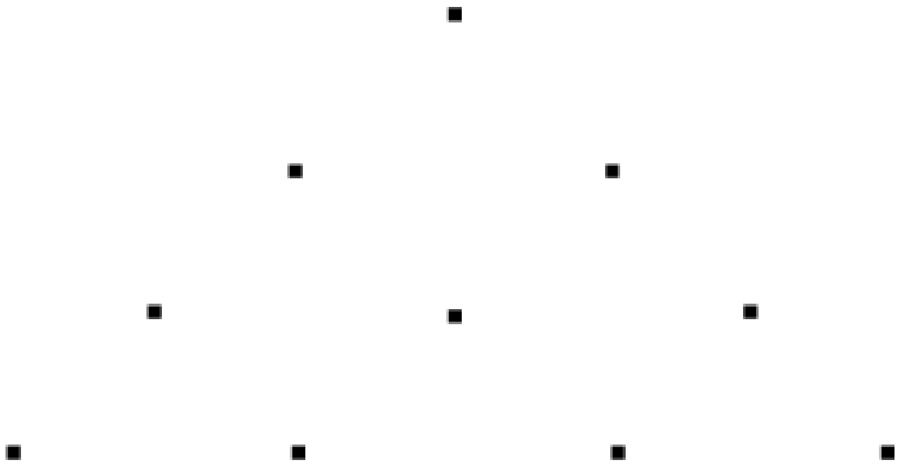
> he looks unto the fixed and eternally immutable realm where… all is orderly and according to reason, and he imitates this realm and, as much as possible, assimilates himself to it… and by association with the divine order becomes himself orderly and divine as far as a human being can…

(*Republic* VII 500c)

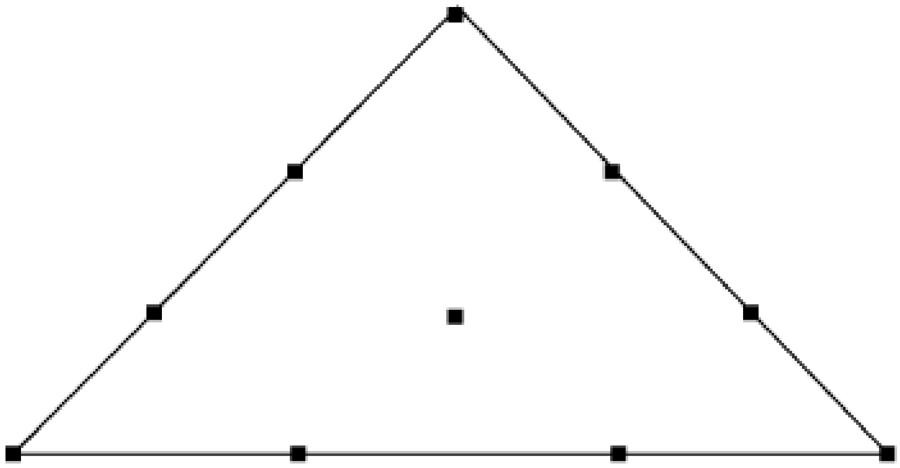
Plato’s philosophic ideal, as well as one of the methods he prescribed to achieve it - namely mathematics - owes much to Pythagoreanism. Pythagoras had taught that life should be in harmony with the divine cosmos (see Pythagoras §2). In Pythagoreanism harmony (*harmonia*) became a central tenet and was explained through numerical relations, possibly in connection with musical theory. For example, the Pythagoreans thought that the motions of the orbiting planets produced a sound which, given the belief that the intervals between the heavenly bodies corresponded to musical ratios, was harmonious. So Aristotle explains the ‘music of the spheres’ - one of several explanations offered for this famous Pythagorean image. Of seminal importance for illustrating the coherence of music and number was the discovery of musical ratios - that music should result when the first four integers of the numerical system, used as components in the harmonic ratios of the octave ($2 : 1$), the fifth ($3 : 2$) and the fourth ($4 : 3$), were imposed upon the continuum of sound. Whether or not Pythagoras, as tradition holds, was the ‘discoverer’ of the musical concords, the Pythagoreans fixed upon the first four numbers as the building blocks of nature. These four sufficed to give extension and shape to bodies in the sequence of point-line-surface-solid:

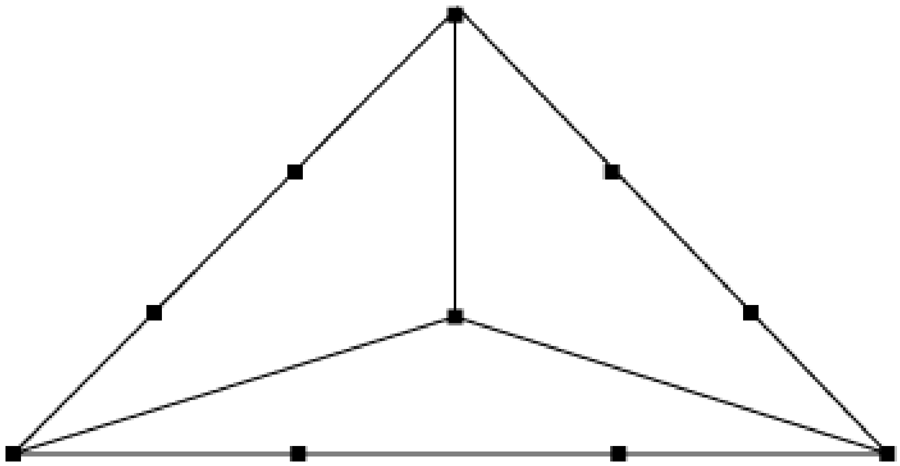


Moreover, the first four integers add up to ten, which the Pythagoreans considered a perfect number and represented in a figure called the *tetraktys*.



From whatever angle one approached the *tetraktys* in counting, the addition always resulted in ten, the basis of the decimal system. The *tetraktys* also produced an equilateral triangle, the simplest plane figure, and a pyramid, the simplest three-dimensional shape.



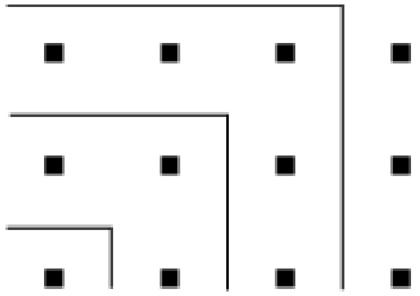


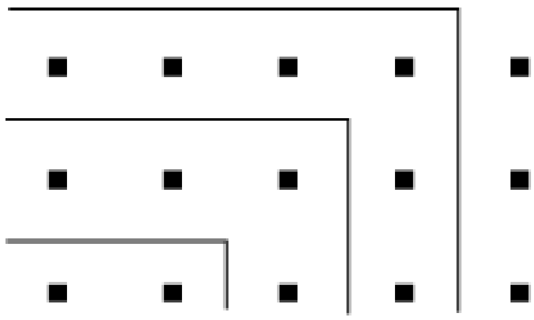
The Pythagoreans viewed the *tetraktys* as a sacred symbol and used it in the following oath: ‘By him [Pythagoras] who handed down to us the *tetraktys*, source and root of everlasting nature’. In short, the Pythagoreans supposed the nature of things could be understood numerically; indeed, some of them apparently went so far as to say that things *are* numbers: ‘…they assumed the elements of numbers to be the elements of all things that exist, and the whole universe to be *harmonia* and number’ (Aristotle, *Metaphysics* 986a2).

Since numbers functioned as the constituent elements of the cosmos, it is important to see how the Pythagoreans understood the nature and generation of number itself. Aristotle again offers the best starting-point:

> The elements of number are the even and the odd, the latter limited, the former unlimited. The One is composed of both of these (for it is both even and odd) and number comes from the one; and numbers… are the whole universe.
>
> (*Metaphysics* 986a17)

How the One can be both odd and even is best explained in the sense that the One, as the first number, is the principle of both odd and even numbers (zero was unknown in Greek mathematics). Thus ‘number comes from the One’, and the generation of number was simultaneously a cosmogonical process since ‘numbers… are the whole universe’. Although in its origin the Pythagoreans viewed the One as both odd and even, limited and unlimited, in its practical application, that is, in its interaction with other numbers, they treated it as odd and limiting. This can be seen in the schema by which the Pythagoreans illustrated the correspondence of odd/even to limited/unlimited. Gnomons (carpenter squares) were placed around an arrangement of points (or pebbles) as follows:





When a gnomon is placed around one point, and the process is continued in sequence, the resulting figure is always of ‘limited’ shape, that is, always a square, whereas when it is placed around two points, the result is a series of oblongs whose sides stand in an ‘unlimited’, that is, an infinite variation to each other. In this scheme the One, as a single unit or point, is equated with the odd. The One is also ranked with limited and odd in the Pythagorean table of ten opposites:

limited	unlimited
odd	even
one	many
right	left
male	female
rest	motion
straight	crooked
light	darkness
good	bad
square	oblong

The position of limited/unlimited at the beginning is not accidental, for their opposition, embodied in the original composition of the One, was considered primal and basic to the development of number and the universe, while the opposition between odd and even can be generally subsumed under this fundamental distinction. The connection of the One with the limited reappears in another Pythagorean text (Aristotle, *Metaphysics* 1091a17), where it is said that the limited (tantamount to the One) ‘breathes in’ and is thus penetrated by the unlimited. In this cosmological fragment the unlimited is equated with the void, to be thought of as infinite space and serving as a dividing principle. The One now becomes a Two (reminiscent of the mythological separation of heaven and earth), which in effect marks the beginning of number, plurality and the existence of discrete physical bodies. The cosmogonic process is sometimes put the other way round: the unlimited is limited (or penetrated) by the limit. This way of stating it brings to the fore the characteristic Greek feeling that what is unlimited, without bounds, is without order and somehow evil (hence ‘bad’ is listed under the unlimited in the above table) and therefore needs to be curtailed and bounded by limit and measure (as the limits of harmonic ratios must be imposed upon the limitless range of sound to produce music). The result, in cosmological terms, is then precisely a *kosmos*, an orderly and structured universe. In so far as the perfected and integral cosmos represents a *harmonia*, a unity stemming from a reconciliation of opposites, Pythagoreanism has a monistic aspect, yet in its source theory it remains essentially dualistic: number comes from the One, and the One is composed of limited and unlimited. From these first two principles everything derives, even though the One, when identified with limit, odd, male, and so on, was felt to be the ‘good’ element in this cosmic dualism. (There can be no question of positing the One as the sole ultimate principle without imposing Platonic and Neo-Pythagorean notions upon early Pythagoreanism.)

Limited und unlimited are the principles of number. Numbers do not merely express the substance, shape and quantitative differences of things but actually appear to constitute bodies of physical dimension. The identification of things with numbers confuses physical bodies with abstractions, or, in Aristotelian terms, the material causes of things with their formal causes. Here Pythagoreanism connects with much of Presocratic thought according to which the source and informing element of the universe was thought of as some kind of matter, be it water, air, fire, earth, or a combination of these (see Archē). At the same time the numerical theories of the Pythagoreans represent a true advance in the history of Greek philosophy: the attempt to explain the nature of things by numbers is a valid philosophical striving to understand the world by its formal or structural principles, even if the Pythagoreans then equated these with the things themselves. And while the Pythagoreans’ interest in numbers was often infused with a mystical element (their solemn veneration of the *tetraktys*) and a primitive number symbolism that blurred distinctions between abstract and concrete (a moral concept such as justice was considered the embodiment of four, a square number of ‘just’, that is, equal reciprocity), no less an authority than Aristotle acknowledged that the Pythagoreans were pioneers and made advances in the mathematical fields (arithmetic, astronomy, harmonics and some geometry). For the ‘Pythagorean theorem’, although long known to Babylonian mathematicians, the Pythagoreans are generally considered to have found the proofs and, although in the wake of this theorem they discovered that the ratios of geometrical figures to each other cannot simply be expressed by a series of rational integers - the discovery of irrational numbers and the principle of incommensurability upset the Pythagorean notion that the world is harmony and number - their very setbacks contributed to subsequent work in Greek mathematics. Plato valued mathematics as a useful discipline to train the philosopher in the perception of eternal and transcendent truth, since in his mind it dealt essentially with invisible and eternally valid realities. By divorcing number from physical substance Plato transforms Pythagorean mathematics, yet few doubt that his

interest in number, arithmetic and measure largely rests upon Pythagorean foundations (consider the mathematical model of the universe in his *Timaeus* (see Plato §16). Plato's immediate successors in the Academy were steeped in Pythagorean number theory (see Speusippus §2; Xenocrates §2).

3 Soul and ethics

Perhaps in no other ancient Greek philosophy is the human being as intimately linked to the cosmos as in Pythagoreanism. Although the correspondence between microcosm and macrocosm, the individual and the universe, is found in much of Greek thought, it received a particularly sharp outline in the Pythagorean view that by assimilation to the divine cosmos the self would come to reflect the cosmic order and harmony. The true self of every person was the soul (see Psychē), the essential element in the partnership of body and soul. Pythagoras' teaching that the soul survived the dissolution of the body and reappeared in other bodies was steadfastly adhered to throughout the history of Pythagoreanism, even if it was sometimes eclipsed by other interests. The doctrine of the immortality and transmigration of the soul translated into a practical and clearly defined way of life that combined ritual purity with high ethical standards and whose precepts were embodied in sayings known as *akousmata* and *symbola* (see Pythagoras §2). The belief in the kinship of all life, as a corollary to the belief in transmigration, imposed a great moral responsibility towards parents, children, friends and fellow citizens, and generally entailed a respectful attitude towards all forms of life in which soul may be embodied; hence the Pythagoreans were, to varying degrees, vegetarians. Their dietary laws were also intended to free them from bodily pollution. The body was seen as a prison, even as a grave (Plato, *Gorgias* 493a) from which the soul was to rise, ever achieving superior reincarnations and culminating in a state of divinity. Thus the Pythagoreans postulated three kinds of rational creatures: 'gods, men, and such as Pythagoras'. Pythagoras was thought to have achieved semi-divine status, which in Greek could be expressed by 'daemon'. It is in a Pythagorean vein that Empedocles (§2) proclaims human beings to be fallen 'daemons'. (A complex 'daemonology' was to become an ingredient of Neo-Pythagoreanism.) The recognition of the religious and moral mandates of the Pythagorean life and of its eschatological meaning constituted wisdom (*sophia*) and the lover of such a life was a *philosophos*, a term that in this sense, as certain traditions report, was first coined in Pythagorean circles.

Qi

A difficult term to contextualize within Western conceptual frameworks, qi *is variously rendered as ‘hylozoistic vapours’, ‘psychophysical stuff’, ‘the activating fluids in the atmosphere and body’, and, perhaps most appropriately, ‘vital energizing field’. In the earlier texts, before the notion came to be adapted to the speculative constructions of the Han cosmologists, it had a significance not unlike the Greek* pneuma *(‘breath’ or ‘animating fluid’). In the ‘cosmological’ speculations of the Han dynasty (206* BC*-*AD *220),* qi *came to be understood as the vital stuff constitutive of all things and was characterized in terms of the active and passive dynamics of* yang *and* yin.

Most individual Western interpretations of the vital and spiritual character of things operated with a physical-spiritual dichotomy; the animating principle was largely distinguishable from the animated things (see Pneuma). In China, the animating fluid is conceptualized in terms of what we would today call an ‘energy field’. This field not only pervades all things, but in some sense is the means or process of the constitution of all things. That is to say, there are no separable ‘things’ to be animated; there is only the field and its focal manifestations. During the period of the Han cosmologists, the notions of *yin* and *yang* came to be used to characterize the dynamics of the transformations which constituted the field of *qi*.

The energizing field as the ‘reality’ of things precludes the existence of forms or ideas or categories or principles which allow for the existence of ‘natural kinds’. Thus, discriminations in the field of *qi* were made in terms of observed and conventionalized classifications associated with diurnal and seasonal changes, directions, colours, body parts and so forth. Processes associated with these correlative classifications were then charted in accordance with the rhythms of the *yang* and *yin*, or active and passive forces (see Yin-Yang).

Perhaps the most important areas in Chinese culture influenced by the notion of *qi* have to do with health, medicine and exercises leading to self-realization. Techniques such as acupuncture and the use of herbal medicines are based upon the understanding of *qi* as that fluid medium which manifests itself in the operations of the human body as well as in the bodily environs. The term ‘body’ must of course be used advisedly; everything is a continuous field of *qi* manifesting itself as both ‘body’ and ‘environs’. The purpose of acupuncture and medicine is to balance the flow of the *qi* such that environs and body are productively continuous one with the other. This productive continuity is achieved by considering the nature of the *qi* manifestation of the human body in terms of the *yin* and *yang* dynamics that are understood to be required for its health. The health of the body is, of course, dependent upon the ‘health’ of the environs. Adjustments of the *yin* and *yang* characteristics through the techniques of acupuncture or the administration of herbals serve to increase or retard the transformations of the *qi* in body and environs.

The *Huangdi neijing (Inner Classic of the Yellow Emperor)* is a pre-Han medical text which employs the sorts of correlative classifications mentioned above to promote a healthy regimen. Among many other advices, it suggests the behaviours associated with the proper response to the particular *qi* of each season. Further, each season is correlated to a part of the body. Inappropriate response to the *qi* of a particular season will harm the bodily organ associated with that season. For example, the *qi* of Spring is ‘coming to life’. In this season one must ‘sleep at night and rise early… relax the body [and] allow intent to come to life.’ Failure to respond thus to the *qi* of Spring will damage the liver and cause one to suffer chills in summer.

Techniques of self-realization have a long history in China, dating from the earliest period of Chinese written records. A fourth century BC meditative piece, ‘Inward Training’, which appears as a chapter in an eclectic work called the *Guanzi* (see Guanzi), contains techniques associated with correct posture, diet and breath control aimed at bringing individuals into harmony with the Way and thereby allowing them to achieve health and long life. Later, Mencius interpreted the field of *qi* in terms of moral energy and offered advice on the attainment of true virtue. Mencius speaks of his ability to nourish his ‘flood-like *qi*’. He describes this *qi* as that which is ‘most vast’ and ‘most firm’ (*Mencius* 2A2). His meaning seems to be, in Western philosophical parlance, that ‘flood-like *qi*’ has the greatest ‘extensive’ and ‘intensive’ magnitude. The language of (extensive) ‘field’ and (intensive) ‘focus’ allows us to understand Mencius as saying that one may nourish one’s *qi* most successfully by making of oneself the most intense focus of the most extensive field of *qi*. In this manner one gains greatest virtue (excellence,

potency) in relation to the most far-reaching elements of one's environs: 'The myriad things are here in me. There is no joy greater than to discover integrity in oneself and to seek virtue through action which persistently mirrors others (*Mencius* 7A4).

The meaning of this familiar passage from the *Mencius* is that 'all things are in me and I am with and in all things'. Recalling the meaning of *qi* as a continuous field, a better rendition might be 'The field of *qi* is focused by me, and thus all *qi* is here in me.'

Qualia

The terms 'quale' and 'qualia' (plural) are most commonly understood to mean the qualitative, phenomenal or 'felt' properties of our mental states, such as the throbbing pain of my current headache, or the peculiar blue of the afterimage I am experiencing now. Though it seems undeniable that at least some of our mental states have qualia, their existence raises a number of philosophical problems.

The first problem regards their nature or constitution. Many theorists have noted great differences between our intuitive conceptions of qualia and those of typical physical properties such as mass or length, and have asked whether qualia could nonetheless be identical with physical properties. Another problem regards our knowledge of qualia, in particular, whether our beliefs about them can be taken to be infallible, or at least to have some kind of special authority.

1 Anti-physicalist arguments

The terms 'quale' and 'qualia' (plural) are most commonly used to characterize what may be called the qualitative, phenomenal or 'felt' properties of our mental states, such as the throbbing pain of my current headache, or the peculiar blue of the afterimage I am experiencing now. Qualitative properties can be more or less specific: the state I am in at the moment can be an example of a migraine, a headache, a pain, or, even more generally, a bodily sensation. Briefly, a mental state is considered to have qualitative properties just in case there is something it is like to be in it.

It seems undeniable that our sensations and perceptions have qualitative properties. However, many philosophers have claimed that the distinctive feels of pains, after-images and other sensations are so radically different from objective properties such as mass or length that they could not be identical with any physical or functional properties of the brain and nervous system. (Indeed, some theorists reserve the term qualia to denote those mental properties, if any, that are irreducibly qualitative: this is why disputes about the metaphysical nature of qualitative properties are sometimes characterized as disputes about whether there are qualia, rather than about what kind of properties qualia, in the metaphysically neutral sense introduced above, could be.) The view that qualitative properties are metaphysically unique has been supported by powerful argument, and may seem to be reinforced by common sense and introspection. If this view is true, however, the existence of qualia will be incompatible with a fully naturalistic account of the mind.

Anti-physicalists have argued against the identity of qualitative with physical (or functional) properties throughout the history of the philosophy of mind, but three arguments have been especially influential since the mid-1970s. The first, modelled upon Descartes' well-known argument for the 'real distinction' between mind and body in the *Sixth Meditation*, (see Descartes, R. §8; Dualism) proposes that one could, under ideal epistemic circumstances, imagine or conceive of the qualitative features of one's pains or perceptions in the absence of any specific physical or functional properties (and vice versa), and that properties that can be so conceived or imagined must be distinct. The second argument proposes that there are qualitative properties of mental states that one could not know about before actually experiencing states of that (or similar) kind, no matter how much knowledge one had about the physical and functional properties of brains and nervous systems: for example, despite having comprehensive knowledge of the relevant sciences, a person raised in an entirely black and white environment would not know what it is like to see red, and despite years of studying bat neuropsychology, we could not know what it is like to be a bat. Moreover, the argument continues, properties that do not afford this sort of knowledge could not be part of the subject matter of any of the objective sciences. The third argument states that no physical or functional characterization of sensations or perceptions could adequately explain why they feel the way they do, and that such an explanatory gap raises doubts about the identification of the properties in question. The conclusion of the first two arguments, of course, is that qualia could not be identical with physical or functional properties, and the conclusion of the third argument is that, at the very least, we have no reason to believe that these identities hold.

Although there are interesting differences between them, these arguments are linked (and can profitably be treated together) in that the first premise of each appears to depend upon the thesis (1) that there is no conceptual connection between qualitative terms or concepts and physicalistic terms or concepts. If there were such a connection, then it would be impossible, if one was fully educated and attentive, to conceive (for example) of a

pain existing apart from the relevant physical or functional property, and it would be possible, at least in principle, to know all there is to know about pain without ever having experienced pain oneself; it would also be easy to explain why it feels a certain way to have the associated physical or functional property. The second premise also appears to depend upon a common thesis, namely, (2) that given this lack of connection, our use of qualitative terms or concepts commits us to (or, at the very least, suggests) the existence of irreducibly qualitative properties.

2 Physicalist responses

Physicalists, in turn, have attempted to deny both (1) and (2). Those denying (1) have argued that, on the contrary, there is a conceptual or epistemic connection between qualitative concepts and physicalist concepts. The candidates here are usually causal, functional or otherwise topic neutral concepts that have at least some claim to be part of our common-sense understanding of these states, since it seems quite implausible to think that physical, neurophysiological or other scientific characterizations could serve as explications of our qualitative concepts (see Mind, identity theory of §3). For example, the concept throbbing headache might be characterized in terms such as 'the state typically caused by a certain range of physical syndromes, and which produces certain desires and (perhaps) behaviour directed towards the abatement of that state', and the concept appearing blue might be characterized in terms such as 'the state typically caused by certain visual stimulations and which typically results in certain similarity judgments and sorting behaviour' (see Functionalism).

Other theorists, however, have doubted that these common-sense causal or functional characterizations could be necessary or sufficient to capture qualitative concepts. The problem with sufficiency is that the attribution of such a characterization to an individual does not seem to close the question of whether they have the quale in question; this is often referred to as the 'absent qualia' objection. The problem with necessity is that some sensations or sensory features of perception seem to have no distinctive causal or functional roles that are sufficiently accessible to be part of our common sense concepts of those states: consider, for example, the strange, though mild, twinge in one's scalp that one felt for the first time yesterday. This leaves two alternatives for physicalists who accept premise (2) and thus wish to argue that there is some sort of conceptual connection between physicalistic and qualitative concepts: they can weaken the constraints on conceptual analysis, so that information from the sciences that may help to individuate sensations and perceptions can make a contribution to the explication of qualitative concepts, or they can deny that there is determinate, coherent content to our qualitative concepts over and above that which can be explicated by classical functionalist or topic neutral characterizations, and thus maintain that there are no corresponding qualitative properties at all (see Eliminativism).

The problem for the first alternative is that it is difficult to make a principled distinction between information that is relevant to conceptual explication and that which is not; defenders of this alternative respond that an important goal of explication in this case is to preserve the intuitive distinctions we make among our mental states, and that any additions to our common lore that enable us to do this (while preserving the bulk of our other commonly held beliefs about these states) will count as relevant to this project. The problem for the second alternative is that it seems counterintuitive to ignore (what seem to be) intuitively evident distinctions among qualitative states just because they cannot be captured in functional or topic-neutral terms that are part of our common knowledge. Defenders of this alternative counsel that we must be wary of judging the worth of a theory in the light of our current intuitions, since intuitions are at least partially shaped by theory and can change over time; they also point to the counterintuitive consequences of accepting a non-physicalist account of the qualitative features of our mental states, and argue that it is not clear which side has the greater burden.

On the other hand, there are many physicalists who agree that at least some qualitative concepts are ineffable, in that they cannot be captured by physical or functional descriptions, or anything other than a demonstrative such as 'feels like that' or 'seems this way to me now'. Nonetheless, they argue, one cannot draw the anti-physicalist conclusion, since the irreducibility of qualitative to physicalistic concepts does not entail the irreducibility of qualitative to physicalistic properties; that is, while accepting premise (1) of the argument against the identity of qualitative and physical or functional properties, they reject premise (2).

Physicalists using this strategy deny the Cartesian claim that our modes of conception can, even under special circumstances, be definitive guides to the nature of things. Properties exist, and are distinct or identical, by virtue of mind-independent facts about the world; the ways we conceive of properties, even clearly and distinctly, have

little to do with these facts. So stated, the argument denies that our conceptualizing has significant metaphysical import. It can be responded, however, that premise (2) is a consequence of the very possibility of reference: that non-equivalent concepts can denote the same item only by picking out different, irreducible, properties of it, and thus that even if 'pain' and 'C-fibre stimulation' did indeed denote the same property, it could only be by virtue of introducing higher-order properties that were themselves distinct. This view of how reference is determined has been considered as received wisdom since its introduction by Frege. But the argument can be countered by challenging the picture of reference it presupposes, and suggesting that the reference of qualitative concepts is determined directly, much as current causal or historical theories of reference propose for the cases of demonstratives, natural kind terms, and proper names (see Reference §4; Proper names). Anti-physicalists, in response, can mount a general challenge to these current theories of direct reference. They can also argue that qualitative concepts are a special case, one in which there is a tighter link between the concepts and the properties they pick out, but such a claim must be argued carefully, so as not to seem *ad hoc*. Alternatively, anti-physicalists can argue that, without some link between concepts (or at least clear and distinct conceptions) and the properties they denote, it would be impossible to have knowledge of metaphysical necessity and possibility at all, and thus, to preserve such knowledge, we must concede that there is at least some presumption that properties clearly and distinctly conceived to exist apart really do so.

Though all physicalists are committed to giving a physicalistic account of sensations and perceptions, those who deny that there are conceptual connections between physicalistic and qualitative concepts can concede that there is something in the realm of the qualitative that may be ineffable or irreducibly subjective, namely, the content of those qualitative concepts. In their view, however, the conceptual irreducibility of qualitative concepts implies neither the ontological irreducibility of the properties they denote nor of the concepts, as mental states, themselves; thus, this conceptual ineffability does not conflict with the physicalist requirement that all mental states and properties be fully describable in the vocabulary of the objective sciences.

Sometimes, in the post-1970s literature on this topic, anti-physicalists claim that it is only by having certain experiences that one can learn new facts about the mental. If this claim is taken to mean that experience alone provides access to a special realm of qualitative properties, then no physicalist can accept it; however, if it is taken to mean that experience affords qualitative concepts with novel content, then physicalists who accept the irreducibility of qualitative to physicalistic concepts can agree. On the other hand, physicalists who believe that qualitative concepts can be given a functional explication maintain that any knowledge we gain uniquely from experience is merely a kind of practical knowledge, or knowing how - a matter of gaining new imaginative or recognitional abilities, rather than concepts that one previously lacked.

3 Our knowledge of qualia and other issues

It is often argued that we have special epistemic access to the qualitative properties of our own mental states: it is claimed that our knowledge of them is infallible, or at least that our beliefs about them have a kind of special authority, and also that these properties are transparent or self-intimating to the minds that experience them. To have infallible knowledge of a class of properties is for it to be logically or conceptually impossible for our (sincere) beliefs about them to be false; to have special authority about a class of properties is for it to be logically or conceptually necessary for most of our (sincere) beliefs about them to be true. A property is transparent or self-intimating if an individual (with adequate conceptual sophistication) cannot help but form accurate beliefs about it whenever it is present. Insofar as they bear these special epistemic relations to those (and only those) who experience them, qualitative properties are importantly different from physical (and classically objective) properties such as shape, temperature and length, about which beliefs may be both mildly and radically fallible. The question naturally arises whether qualitative properties, if they have the above-described epistemic features, could be physical, functional or otherwise objective nonetheless.

Functionalists can accommodate infallibility or special authority and transparency, since according to (at least some versions of) this doctrine, states with qualitative properties and the beliefs they produce are interdefined. Thus, as a matter of conceptual necessity, no state will count (for example) as an instance of pain unless it produces (either always or for the most part) the belief that one is in pain, and, conversely, no state will count as a belief that one is in pain unless it is actually produced by pain.

Nonfunctionalist physicalists, on the other hand, cannot point to a definitional connection between qualitative

properties and an individual's beliefs about them. Thus, some theorists merely reject infallibility and transparency, arguing that we can and do make sincere and unambiguous errors about our experiences (and fail to notice some of their properties) when we are tired and inattentive, or when misinformation skews our expectations about the experiences we are soon to have. It is more difficult, however, to argue that one can make such mistakes in the absence of these mitigating factors. Thus, many physicalists have attempted to show that at least some sort of special epistemic access to qualia is compatible with their metaphysical views.

For example, some philosophers have argued that a certain sort of introspective accuracy is insured by the proper operation of our cognitive faculties, and thus that, as a matter of law, we cannot be mistaken about (or fail to notice certain properties of) our mental states. On a view such as this, the claim that we are infallible about our mental states (or that they are transparent to us) will be nomologically necessary, but not necessary in any stronger sense. However, on nonfunctionalist physicalist views that treat qualitative concepts as demonstrative, certain statements of infallibility can be logically or conceptually necessary, in that one cannot be wrong, on any particular occasion, to think that one's current mental state feels like that. Even so, one cannot be sure, on these views, that all states that appear to be of the same phenomenal type are in fact of that same phenomenal - that is, physical - type. Since this sort of infallibility does not guarantee that one has re-identified a single phenomenal type on different occasions, it cannot provide any substantive assurances about the nature or reality of our mental states.

There are other interesting issues about qualia which are worth mentioning, though their full discussion is beyond the scope of this entry. One involves the range or extent of their occurrence. Bodily sensations and perceptions, the most common examples of states with qualia, are often contrasted with beliefs and desires, in that the former are taken to be essentially qualitative, the latter essentially intentional (that is, purporting to be about items or events in the world) (see Bodily sensations; Perception; Intentionality; Propositional attitudes). Some theorists dispute this distinction, arguing that true intentional states must have qualitative properties as well. But whether or not intentional states must also be qualitative, it certainly seems (for occurrent beliefs and desires) that there is something it is like for us, if not all creatures, to have them. If so, then the issues raised in giving a physicalistic account of sensations and perceptions will be relevant for intentional states as well.

A related issue is whether all sensations and perceptions are indeed essentially qualitative, or whether, instead, there could be perception without qualia; that is, whether there could be bona fide perceptual states that are unconscious, such that there is nothing it is like to be in them at all.

Yet another question is whether (and if so, how) the myriad qualia we seem to experience at any given time are bound together at a given moment, and continuous with our experiences at previous and subsequent times, or whether the common sense view that we enjoy a unity of consciousness and a stream of consciousness is rather an illusion to be dispelled.

Quantification and inference

Quantificational reasoning in natural languages contains occurrences of expressions which, though name-like from a syntactic perspective, intuitively seem to be importantly different from ordinary names. For example, in attempting to argue that every F is G, we might consider an 'arbitrary' F, give 'it' the 'name' 'n', and go on to argue that n is G. That such an occurrence of 'n' is somehow different from occurrences of ordinary names can be seen by noting, for example, that arguing from the claim that Bertrand Russell is F to the claim that Bertrand Russell is G in general does not suffice for drawing the conclusion that every F is G. Similarly, given that some F is G, in general we do not think it legitimate to assert that Bertrand Russell is F and G, and continue reasoning from that claim. It seems that such occurrences of 'n' differ semantically from similar occurrences of ordinary names. Thus the question arises as to the semantics of occurrences of such expressions. An adequate semantic account must justify appropriate inferences to and from sentences containing these terms.

1 Condition of adequacy

Natural languages contain quantificational reasoning employing expressions which function syntactically, but not semantically, as proper names. For example, in attempting to argue that every *F* is *G*, we might consider an 'arbitrary' *F*, give 'it' the 'name' '*n*', and go on to argue that *n* is *G*. Or, having been given that some *F* is *G*, we give the 'name' '*n*' to an arbitrary *F* that is *G*, and go on to draw further conclusions concerning *n*. It will help to shed light on these terms in natural language arguments if we turn our attention to systems of natural deduction for first-order logic (see Natural deduction, tableau and sequent systems). For such systems contain rules which more or less mimic these natural language forms. Though formulations vary significantly, many systems have a 'universal generalization' (UG) rule which licenses the inference of '$(\forall x)\phi(x)$' from '$\phi(a)$' subject to certain restrictions, and an 'existential instantiation' (EI) rule which allows one to infer '$\phi(a)$' from '$(\exists x)\phi(x)$', again subject to restrictions. We shall call singular terms in systems of natural deduction which play the role played by '*a*' above 'instantial terms'. Instead of discussing terms such as '*n*' in our natural language examples, we can ask about the proper semantic treatment of instantial terms in systems of natural deduction. The regimentation and explicitness of structure of natural deduction will enable us to state conditions of adequacy precisely and to see whether those conditions are met by particular semantic theories.

As in natural language, instantial terms in natural deduction appear to behave differently from names or 'individual constants'. Both UG and EI fail to be truth-preserving if the instantial term is an individual constant. Of course, in many formulations of natural deduction, expressions from the syntactic category of individual constant (or individual variable) are pressed into service as instantial terms in applications of UG and EI. However, this probably results more from the desire not to have an additional category of singular terms than from any view about the appropriate semantics for instantial terms.

Before discussing conditions of adequacy for semantic theories of instantial terms, let us consider the view that there can be no semantic theory for instantial terms, because occurrences of formulas in applications of UG and EI which contain instantial terms should not be thought of as having any meaning. On this view, UG and EI have a certain utility in that they allow us to move from meaningful formulas to other meaningful formulas (and soundness and completeness results for systems employing these rules justify their use), but it is a mistake to think that formulas containing instantial terms in applications of UG and EI themselves have any meaning. Whatever attraction this view may have as an account of formulas containing instantial terms in formal systems, it seems quite implausible as an account of natural language sentences containing the analogues of these terms. For surely sentences containing such terms in natural language arguments are meaningful: as we read an argument containing these terms, we understand the claims made by the sentences containing them.

In an adequate semantics all allowable inferences must be truth-preserving. That is, the truth-conditions assigned to a formula must be such that, should they obtain, then so will the truth-conditions of any formula properly inferred from it. So in so far as we provide a semantics for instantial terms and the formulas containing them, it ought to account for the inferential relations such formulas manifest. Let us call this property of a semantics 'inferential adequacy'. It is important to appreciate the difference between inferential adequacy and classical completeness and soundness results. Quine's system of deduction ([1950] 1982) is illustrative. Quine defines a

'finished derivation' as a derivation whose last line neither contains an instantial term (a 'flagged variable', in his terminology) nor depends on a premise which contains an instantial term. He then proves what he calls soundness; that the premises imply the last line of a finished derivation. However, Quine provides no semantics for instantial terms that is inferentially adequate. As he himself remarks, UG and EI are not 'implicative' relative to the only semantics he gives (which essentially treats instantial terms as names).

An inferentially adequate semantics must assign distinct truth-conditions to occurrences of the same formula in different derivations. For suppose ' $(\forall x)\phi(x)$' is correctly inferred from ' $\phi(a)$' in some derivation. Inferential adequacy requires the truth-conditions of this occurrence of ' $\phi(a)$' to be such that it entails ' $(\forall x)\phi(x)$'. On the other hand, an occurrence of ' $\phi(a)$' in a derivation where it is correctly inferred from ' $(\exists x)\phi(x)$' must be assigned truth-conditions such that it is entailed by the latter. Thus ' $\phi(a)$' must have different truth-conditions in the two derivations.

There are different sorts of cases in which a given formula must be assigned different truth-conditions as it occurs in different derivations. Consider the following example.

(A)	(B)
$(1)(\forall x)(\exists y)Fxy$	$(1)(\exists y)(\forall x)Fxy$
$(2)(\exists y)Fay$	$(2)(\forall x)Fxb$
$(3)Fab$	$(3)Fab$
$(4)(\exists w)Faw$	$(4)(\forall z)Fzb$
$(5)(\forall z)(\exists w)Fzw$	$(5)(\exists w)(\forall z)Fzw$

In derivation (A), inferential adequacy requires that '*Fab*' is logically equivalent to ' $(\forall x)(\exists y)Fxy$', from which it is inferred. In (B) it must be logically equivalent to ' $(\exists y)(\forall x)Fxy$'. Note that this is unlike the previous case in that it is not simply a matter of (for example) ' $\phi(a)$' being inferred from ' $(\exists x)\phi(x)$' in one case and having ' $(\forall x)\phi(x)$' inferred from it in another. In both (A) and (B) a formula containing '*a*' has a universal generalization (on the place occupied by '*a*') inferred from it.

2 Three semantic theories of instantial terms

Three semantic accounts of instantial terms have been shown to satisfy the requirement of inferential adequacy. Though other inferentially adequate accounts can be imagined, we shall consider only these three. The first holds that in addition to individual people, numbers and so on there are 'arbitrary' people, numbers and so on. (An arbitrary number has every property common to all numbers, and so on.) Instantial terms are names of these arbitrary or indefinite objects. Prior to Frege's attack on such views (1904), they were widely held and are still sometimes suggested by informal comments accompanying the introduction of UG and EI in logic textbooks. Kit Fine (1985a) has made the view respectable by formulating a precise and powerful version that is inferentially adequate. On Fine's formulation, which arbitrary object a given instantial term names is determined by features of the derivation in which it occurs. An arbitrary object is associated with a range of individual objects (an arbitrary number is associated with a range of individual numbers, and so on), and a predicate is true of the arbitrary object just in case it is true of each individual object in the range. It is this which allows ' $\phi(a)$' to entail ' $(\forall x)\phi(x)$' under the appropriate conditions.

A second account of the semantics of instantial terms holds that they are actually quantifiers. On this view, instantial terms are expressions of generality just like ordinary quantifiers except that the quantifications they express and the scope relations they have to each other are determined by linguistic context. So, for example, in (A) and (B) above, features of the derivations determine whether '*a*' and '*b*' express universal or existential quantifications, and whether '*a*' or '*b*' has wider scope ('*a*' has wide scope in (A) and narrow scope in (B) relative to '*b*'). On this view, suggested in Wilson (1984) and formulated as inferentially adequate in King (1991), we might say that instantial terms are 'context-dependent quantifiers', thus emphasizing both that they express quantifications and that the quantifications they express and the relative scopes of those quantifications vary with the linguistic context. On such a view, ' $\phi(a)$' entails ' $(\forall x)\phi(x)$' (under the appropriate conditions) because ' $\phi(a)$' itself expresses a quantified claim.

The third view is that instantial terms are to be thought of as ε-terms. Hilbert introduced the ε-operator as a variable-binding operator used to form terms: if 'ϕ' is a formula (some presentations require 'ϕ' to contain free '*x*'), then '$\varepsilon x\phi$' is a singular term. Though Hilbert provided no explicit semantics for singular terms formed using the ε-operator, he remarked that '$\varepsilon x\phi$' should be thought of as denoting an arbitrary element in the domain satisfying 'ϕ' if anything does (if nothing satisfies 'ϕ', the term can be thought of as denoting any element in the domain). Further, Hilbert provided the following axiom to govern ε-terms: $(\exists x)\phi(x) \rightarrow \phi(\varepsilon x\phi)$. This axiom justifies the following rules of inference for ε-terms: (1) infer '$\phi(\varepsilon x\phi)$' from '$(\exists x)\phi(x)$'; and (2) infer '$(\forall x)\phi(x)$' from '$\phi(\varepsilon x{\sim}\phi)$'. Thus Hazen (1987) considers constructing a system of natural deduction in which (1) and (2) replace EI and UG respectively, but in which we abbreviate the ε-terms used in applications of (1) and (2) by single letters. Derivations using such abbreviations would be indistinguishable from those in Quine's (1950) system. A semantics for ε-terms of the sort given in Leisenring (1969) would result in an inferentially adequate theory.

Which of the three views discussed above is ultimately preferable appears to depend on philosophical and methodological considerations. In fact, it is not clear how different the views really are. One might well complain that arbitrary objects are unnecessary intermediaries, and that the ranges of individuals with which they are associated do all the real semantic work. But when arbitrary objects are eliminated from the first view and instantial terms are directly associated with ranges of individuals, the first and second views begin to look quite similar. In addition, since, following Hilbert, we can use ε-terms to 'define' the quantifiers ($(\forall x)\phi(x) \leftrightarrow \phi(\varepsilon x{\sim}\phi)$ and $(\exists x)\phi(x) \leftrightarrow \phi(\varepsilon x\phi)$), it is unclear whether the difference between the second view (instantial terms are quantifiers) and the third view (instantial terms are ε-terms) is substantive.

Quantifiers

The quantifiers 'some' and 'every' were the object of the very first logical theory, Aristotelian syllogistic. An example of a syllogism is 'Every Spartan is Greek, every Greek is European, therefore every Spartan is European'. In such inferences, no quantifier is governed by another one. Contrast this with 'Everybody loves somebody'. Modern logic is often taken to have begun when Frege systematized for the first time the logic of quantifiers, including such dependent ones. In general, much of what has passed as logic over the centuries is in effect the study of quantifiers. This is especially clear with the area of logic variously known as quantification theory, lower predicate calculus or elementary logic. Some philosophers have even sought to limit the scope of logic to such a study of quantifiers. Yet the nature of quantifiers is a delicate matter which is captured incompletely by the logic initiated by Frege and Russell.

1 Interpretation of the quantifiers

Traditionally, quantifiers have been taken to be those expressions which somehow indicate the size of the extension of a predicate (see Logic, ancient §§1-3; Predicate calculus), for example, expressions such as 'some' (the existential quantifier), 'every' (the universal quantifier), the numerical quantifiers 'one', 'two', 'three',…, 'many', 'few' and so on. The logical properties of the existential and universal quantifiers are studied in quantification theory or first-order logic. The numerical quantifiers are definable in terms of the existential and universal quantifiers, unlike quantifiers such as 'many' and 'few'. For this reason the latter are sometimes called nonstandard quantifiers. Here we shall be concerned mainly with the standard quantifiers 'some' and 'every'. When such quantifiers are applied to higher-order entities (predicates, relations, functions, predicates, relations and functions of predicates, relations and functions and so on), we are dealing with higher-order quantifiers (see Second- and higher-order logics).

The formulas of a first-order language *L* are built out of a set of nonlogical constants and individual variables by means of propositional connectives, the identity symbol and quantifiers. Typically, the formation rules for quantifiers allow us to take a formula with a free variable *x* and to prefix to it the existential quantifier '$\exists x$' or the universal quantifier '$\forall x$'. The formula is then called the 'scope' of the quantifier in question (see Scope). In the resulting formula - for example, $(\exists x)(\ldots x \ldots)$ - the variable *x* is said to be 'bound' by the quantifier '$\exists x$'. The nonlogical constants can be predicates, function symbols or individual constants.

A first-order formal language allows us to systematize the laws of quantification. Usually, a number of logically true (valid) formulas are assumed as logical axioms and a number of rules of inference are used to derive other logical truths (ideally, all of them) as theorems. A complete axiomatization of ordinary quantification theory was first given by Gödel in 1929. A theoretically more illuminating completeness proof was given by Henkin in 1949.

Quantification theory must be considered semantically, not only as a purely formal system. To specify the meaning of an interpreted first-order sentence is to specify its truth-conditions. Usually, such a specification of truth-conditions is done step by step, starting from inside, and at each step indicating how the truth or falsity of an expression depends on the truth or falsity of its component expressions. Such specifications of meaning are said to satisfy the principle of 'compositionality' (see Compositionality).

Any specification of truth-values must be relative to a model of the underlying language. The set of elements (individuals) of this model is called its domain. A quantifier is often said to range over this domain.

The truth-value of an interpreted and quantified sentence, say, $(\forall x)(\ldots x \ldots)$, cannot be specified in terms of the truth-value of the formula $(\ldots x \ldots)$, for the latter contains a free variable and hence does not have a truth-value. The truth-value of $(\forall x)(\ldots x \ldots)$ therefore has to be defined as a function of all the substitution instances of $(\ldots x \ldots)$ or else through the other semantic attributes of $(\ldots x \ldots)$. Tarski, who was the first to formulate an explicit truth-definition for quantificational languages (1933), chose the latter course and defined truth for first-order languages via the notion of satisfaction, so preserving the compositionality of his procedure (see Tarski's definition of truth).

Tarski's truth-definition is a formal specification of truth-conditions of sentences containing quantifiers, not yet a genuine interpretation of quantifiers. There are three main interpretations of quantifiers in the literature.

(A) *Quantifiers as higher-order predicates*. On this view, what, for example, the existential quantifier does in a sentence such as

(1) $(\exists x)S(x)$

is to say that the complex or simple predicate *S*(*x*) is not empty. This is the approach we described above and is *prima facie* quite natural. It goes back to Frege. Its most important systematization and further development is the theory of so-called generalized quantifiers, currently the dominant trend in the study of quantifiers among theoretical linguists (see Quantifiers, generalized).

(B) *Substitutional interpretations of quantifiers*. On such an interpretation, the import of a sentence such as (1) is explained in terms of the set of different substitution-instances of the open formula S(x) (see Quantifiers, substitutional and objectual).

(C) *Quantifiers as choice terms*. The basic idea can be explained by example. A natural interpretation of the sentence

(2) Every man owns a dog

is to say that for any man given to one, one can choose a dog such that the given man owns the chosen dog. In the formal counterpart of (2),

(3) $(\forall x)(\exists y)O(x, y)$,

we would say that, for every value of *x*, one can find a value of *y* such that *O*(*x*, *y*). We can say that on this view quantifiers codify suitable choice terms. This way of interpreting quantifiers is systematized and generalized in Hintikka's game-theoretic semantics (see Hintikka and Sandu 1996).

2 The game-theoretic approach

In this game-theoretic treatment, a sentence such as (3) above is interpreted via a semantic game played by 'myself' (the initial verifier) against 'nature' (the initial falsifier), the former trying to produce true sentences while the latter is striving for the contrary. The universal quantifier '$\forall x$' in (3) marks a move by 'nature', who must choose an individual, say *d*, from the universe of the model in which (3) is evaluated, and the existential quantifier '$\exists y$' marks a move by 'myself', who must also choose an individual, say *e*. The sentence (3) is defined to be true if 'myself' has a method (usually codified by a mathematical function *f*) which, for every individual *d* chosen by 'nature' gives him the 'right' choice *e*, that is, $O(d, e)$ holds. More precisely, $O(d, f(d))$ holds (see Semantics, game-theoretic).

The central notion involved in interpretation (C) is that of a strategy, that is, a rule which specifies which move a player is to make in any possible situation which might come up in the game. The idea of an 'independent' quantifier is captured by that of an informationally independent choice. For instance, in (3) the choice of a value of y depends on the choice of a value of *x* in the sense that the choice connected with y is made on the basis of the player's knowledge of the value that was chosen for *x*, but not vice versa. In the jargon of game-theory, a game associated with a sentence of ordinary first-order language is one of perfect information.

In the usual formal (but interpreted) first-order languages, the three interpretations (A)-(C) assign the same truth-value to each sentence. Nevertheless, several things distinguish (C) from (A) and (B).

First, only interpretation (C) does justice to the fact that the expressive power of first-order languages lies in the dependence of quantifiers on each other. To understand first-order logic is, in this sense, to understand the idea of a dependent quantifier. In contrast, in (A) and (B), quantifiers are considered in isolation from each other. Interpretations of type (C) guided the work of David Hilbert and his school in the 1920s and 1930s see (Hilbert and Bernays 1934) and similar views have enjoyed a widespread albeit inconspicuous currency in mathematical practice.

Second, (C), unlike (A), yields a non-compositional interpretation of the standard quantifiers. An existential quantifier '$\exists y$' is interpreted in (C) by a choice function whose arguments are certain universally quantified

variables. Which ones they are depends on the context.

Interpretation (C) offers an interesting possibility of generalizing quantification theory (first-order logic). If one understands the idea of a dependent quantifier as illustrated by (3), one *ipso facto* understands the idea of an independent quantifier. What often passes unnoticed is that the usual nested ordering of scopes for first-order logic rules out certain perfectly possible and understandable patterns of mutual dependence and independence between quantifiers, in that it is required that the scopes of two different quantifiers are either exclusive or nested, that is, that their scopes do not overlap only partially.

But what happens when this arbitrary restriction is given up? As an example, consider the first-order formula

(4) $(\forall x)(\exists y)(\forall z)(\exists w)S(x,y,z,w)$.

The question is what happens if in (4) we require '$\exists w$' to be within the scope of '$\forall z$' but not in that of '$\forall x$'? There is no way of expressing this complex of dependencies in the usual linear notation of first-order logic. For that purpose, a different notation has to be introduced. A special kind of informational independence has been studied by logicians under the title of 'branching quantifiers'. They were introduced by Henkin in 1959. A more general way of indicating independence is to use a slash notation:

(5) $(\forall x)(\exists y)(\forall z)(\exists w/\forall x)S(x,y,z,w)$.

The idea here is that the last existential quantifier does not depend on '$\forall x$'.

What can be said of quantifiers can also be said, *mutatis mutandis*, of disjunctions and conjunctions: the independence indicator slash can be applied to them too. The languages using the slash notation are called independence-friendly first-order languages.

Neither approach (A) nor approach (B) works for independence-friendly first-order languages. The reason is that such a language involves context dependencies which make a compositional interpretation unrealistic. For a compositional interpretation requires that the meaning of an expression be specified in terms of its component parts. This is not the case with the expression $(\exists w/\forall x)S(x,y,z,w)$ in (5), for its interpretation makes reference to an element '$\forall x$' which occurs outside it.

In contrast, interpretation (C) extends naturally to cover this new language. All we need is to drop the requirement that the semantic game associated with a sentence such as (5) is one of perfect information.

What has been said has a number of consequences not usually noted in the study of quantifiers.

(1) The meaning of quantifiers is often explained in terms of their 'ranging over' a set of entities. Such an explanation presupposes an interpretation along the lines of (A) or (B) and hence is not a general explanation of the meaning of quantifiers.
(2) The notion of quantifier scope is ambiguous. The usual formal scope notation indicates two different things. On the one hand, it indicates the relative logical priority of different quantifiers (and connectives); on the other, it indicates the segment of a formula (or a discourse) in which a variable is bound by a given quantifier. There is no reason to expect that these two always go together, and in natural languages they seem to involve entirely different mechanisms.
(3) Certain types of quantifiers, namely informationally independent ones, do not admit of a natural compositional truth-definition, but have to be treated in other ways semantically.
(4) A general theory of quantification will have to comprise more than is currently known as quantification theory or ordinary first-order logic.
(5) Since independence-friendly first-order logic is not axiomatizable, it is unrealistic to expect the logic of quantifiers to admit of a complete systematization.
(6) The logical behaviour of quantifiers in natural languages seems to differ more radically from ordinary formal first-order logic than has usually been recognized.

Quantifiers, generalized

Generalized quantifiers are logical tools with a wide range of uses. As the term indicates, they generalize the ordinary universal and existential quantifiers from first-order logic, ' $\forall x$*' and '* $\exists x$*', which apply to a formula A(x), binding its free occurrences of x.* $\forall x A(x)$ *says that A(x) holds for all objects in the universe and* $\exists x A(x)$ *says that A(x) holds for some objects in the universe, that is, in each case, that a certain condition on A(x) is satisfied. It is natural then to consider other conditions, such as 'for at least five', 'at most ten', 'infinitely many' and 'most'. So a quantifier Q stands for a condition on A(x), or, more precisely, for a property of the set denoted by that formula, such as the property of being non-empty, being infinite, or containing more than half of the elements of the universe. The addition of such quantifiers to a logical language may increase its expressive power.*

A further generalization allows Q to apply to more than one formula, so that, for example, Qx(A(x),B(x)) states that a relation holds between the sets denoted by A(x) and B(x), say, the relation of having the same number of elements, or of having a non-empty intersection. One also considers quantifiers binding more than one variable in a formula. Qxy,zu(R(x,y),S(z,u)) could express, for example, that the relation (denoted by) R(x,y) contains twice as many pairs as S(z,u), or that R(x,y) and S(z,u) are isomorphic graphs.

In general, then, a quantifier (the attribute 'generalized' is often dropped) is syntactically a variable-binding operator, which stands semantically for a relation between relations (on individuals), that is, a second-order relation. Quantifiers are studied in mathematical logic, and have also been applied in other areas, notably in the semantics of natural languages. This entry first presents some of the main logical facts about generalized quantifiers, and then explains their application to semantics.

1 The general concept

A (generalized) quantifier is a relation between relations on individuals (in other words, a second-order relation). Its *type*, a finite sequence of positive numbers, indicates how many relations and of what degree. For example, a quantifier of type $\langle 2,1,1,4\rangle$ is a relation between one binary relation (that is, a relation of order 2), two sets and one four-place relation. Let *M* be a non-empty universe. Then define a (local) quantifier of type $\langle 2,1,1,4\rangle$ *on M* to be any relation between a binary relation on *M*, two subsets of *M* and a four-place relation on *M*. Then a (global) quantifier *Q* of type $\langle 2,1,1,4\rangle$ is a function which associates with each universe *M* a quantifier Q_M of the same type on *M*.

The quantifiers '$\forall$' and '$\exists$' are thus of type $\langle 1\rangle$. Below are definitions of these and some other type $\langle 1\rangle$ quantifiers, with *M* any universe, *A* any subset of *M*, and $|A|$ the cardinality of *A* (Q^R is called the Rescher quantifier):

$$\begin{aligned}
\forall_M A &\Leftrightarrow A = M \\
\exists_M A &\Leftrightarrow A \\
(\exists_{\geq 5})_M A &\Leftrightarrow |A| \geq 5 \\
(\exists_{\leq 10})_M A &\Leftrightarrow |A| \leq 10 \\
(Q_0)_M A &\Leftrightarrow A \\
(Q^R)_M A &\Leftrightarrow |A| > |M - A|
\end{aligned}$$

Here are some more examples of quantifiers (types are written to the left):

$$\begin{array}{ll}
\langle 1,1\rangle & \mathrm{I}_M AB \Leftrightarrow |A| = |B| \quad \text{(the Härtig quantifier)} \\
\langle 1,1,1\rangle & \mathit{more\ldots than}_M ABC \Leftrightarrow |A \cap C| > |B \cap C| \\
\langle 2\rangle & \mathrm{W}_M R \Leftrightarrow R \text{ is a well-order of } M \\
\langle 2,2\rangle & \mathrm{IG}_M RS \Leftrightarrow R \text{ and } S \text{ are isomorphic graphs}
\end{array}$$

The notion of a type $\langle 1\rangle$ quantifier was introduced by Andrzej Mostowski (1957), and extended to arbitrary types by Per Lindström (1966). Aristotle's syllogisms (see Logic, ancient §§1-3) involve type $\langle 1,1\rangle$ quantifiers, a natural class, as will be seen in §3. The general notion of quantifiers as variable-binding operators denoting

second-order relations was in fact explicit in Frege's work, except that Frege did not relativize to an arbitrary universe (see Frege, G. §6).

The quantifiers above share an important property, closure under isomorphism (or ISOM). We use the following notation: a function *f* from a set *X* to a set *Y* is 'lifted' to subsets *A* of *X*, or to (for example) ternary relations *R* on *X*, by $f(A)=\{f(a)\colon a\in A\}$ and $f(R)=\{(f(a),f(b),f(c))\colon (a,b,c)\in R\}$. Now for a quantifier *Q* of type $\langle 2,1,1,4\rangle$, say, define *Q* to be *closed under isomorphism* if whenever *f* is a bijection from *M* to M' (a one-one function from *M* onto M'), and *R*, *A*, *B*, *S* are appropriate arguments for Q_M,

$$Q_M RABS \Leftrightarrow Q_{M'} f(R)f(A)f(B)f(S).$$

ISOM says that *Q* does not care about the individual elements of a universe, only about their 'structure' with respect to the relational arguments. This allows quantifiers to be treated as logical constants (see §2 below; Logical constants §3). ISOM has a particularly clear meaning for quantifiers which relate sets, so-called 'monadic' quantifiers (that is, of type $\langle 1,1,\ldots,1\rangle$). It then says that *Q* only cares about the cardinalities of these sets (and sets that can be formed from them by taking unions, intersections and complements), not the sets themselves. For example, for a type $\langle 1,1\rangle$ quantifier, ISOM is equivalent to the following condition:

If $A,B\subseteq M$, $A',B'\subseteq M'$, $|A\cap B|=|A'\cap B'|$, $|A-B|=|A'-B'|$, $|B-A|=|B'-A'|$, and $|M-(A\cup B)|=|M'-(A'\cup B')|$, then $Q_M AB \Leftrightarrow Q_{M'} A'B'$.

Thus, in the monadic case, ISOM quantifiers deal with *quantities*, as the name suggests they should. Indeed, such a quantifier can be redefined as a relation between numbers; the examples above provide illustrations.

2 Quantifiers in logic

Generalized quantifiers are easy to add as new logical constants to first-order logic, FO. For example, '*A* is finite' cannot be expressed in FO, but if we add the quantifier Q_0 above, the sentence $\neg Q_0 xPx$ expresses precisely that the denotation of *P* is finite. If *Q* is a quantifier of type $\langle 2,1,1\rangle$, say, the logic FO(*Q*) is formed from FO by adding a formation rule allowing formulas of the form

(1) $Qxy,z,u(A(x,y),B(z),C(u)),$

where $A(x,y)$, $B(z)$ and $C(u)$ are formulas. Free occurrences of the indicated variables become bound in (1). To interpret (1) in a model M with universe *M*, note that relative to M and the variables *x*, *y* (and a variable assignment which we suppress here), $A(x,y)$ denotes a binary relation $A(x,y)^{\mathrm{M}}$ on *M*, namely, the set of pairs (a,b) such that $A(a,b)$ holds in M. Then, (1) is defined to be true in M if and only if $Q_M A(x,y)^{\mathrm{M}} B(z)^{\mathrm{M}} C(u)^{\mathrm{M}}$. This generalizes the usual clauses for $\forall xA(x)$ and $\exists xA(x)$ in the truth-definition for FO. Logical consequence in FO(*Q*) is defined as usual (the conclusion must be true in every model of the premises - see Model theory). And just as FO can be used to formulate theories, like arithmetic or group theory (first-order theories), so can FO(*Q*). The properties of these theories, and of the consequence relation, will of course depend on *Q*.

Similarly, one defines logics of the form FO($Q_1,\ldots,Q_n$). This is a model-theoretic conception of a logic as given roughly by a class of sentences, a class of models and a truth-relation between them (in contrast, a proof-theoretic conception would emphasize a formal inference system). Some basic constraints apply; for example, only ISOM quantifiers are considered.

Abstract model theory studies the properties of model-theoretic logics in general, logics with generalized quantifiers being prime examples. Among interesting properties of a logic *L* are axiomatizability (existence of a formal inference system proving precisely the valid sentences of *L*), compactness (if every finite subset of a set Φ of *L*-sentences has a model then the whole of Φ has a model) and the Löwenheim property (if an *L*-sentence has an infinite model it has a denumerable model; see Löwenheim-Skolem theorems and nonstandard models §§2, 3). FO has these properties and several stronger properties as well, and a celebrated result of abstract model theory is that such properties in fact characterize FO. To state this one needs a way to compare the expressive power of various logics. A logic L' is said to be an extension of a logic *L*, $L\leq L'$, if everything that can be said in *L* can also be said in L', in other words if for every *L*-sentence there is a logically equivalent L'-sentence (one with the

same models). Also, $L \equiv L'$ if $L \leq L'$ and $L' \leq L$. Note that if *L* is a logic with generalized quantifiers, FO $\leq L$. Given a simple assumption about these quantifiers, one can prove the following result (Lindström's theorem):

If *L* is either compact or axiomatizable, and has the Löwenheim property, then $\mathrm{FO} \equiv L$.

Thus, increase of expressive power entails loss of some of FO's properties. For example, if '*A* is finite' is expressible in *L*, it can be seen that *L* can be neither compact nor axiomatizable. But there do exist compact and axiomatizable proper extensions of FO (hence the Löwenheim property fails for them), the simplest example being FO(Q_1), where Q_1 is the quantifier 'there exist uncountably many'. Extending FO should be done with care, to strike a balance between expressive power and model-theoretic behaviour.

How many different quantifiers (of a given type) are there? Locally, the rough answer is: many times more than the size of the universe (see Westerståhl 1989: §4.6 for more detail). For example, if *M* has *n* elements, then there are 2^{4^n} type $\langle 1,1 \rangle$ quantifiers on *M*. So there are $2^{16} = 65{,}536$ type $\langle 1,1 \rangle$ quantifiers on a universe with 2 elements! Counting only ISOM quantifiers the number is 1,024, still large compared to 2. As to global quantifiers, even if we restrict attention to finite universes there are uncountably many ISOM quantifiers of each type.

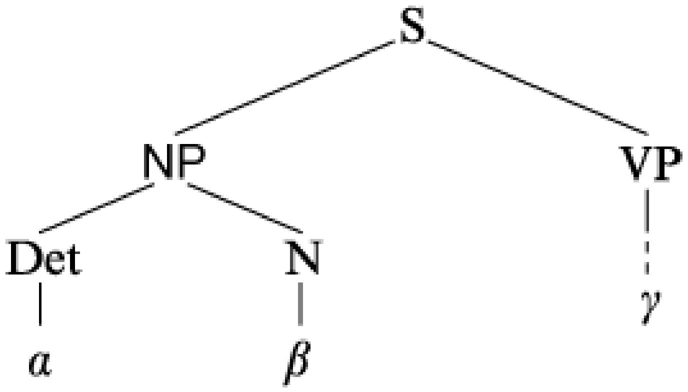
Some of these different quantifiers will have the same expressive power. For example, $\exists_{\geq 5}$ is definable in FO, so FO $(\exists_{\geq 5}) \equiv$ FO. In general, a quantifier *Q* is said to be definable in a logic *L* if it is defined by some *L*-sentence whose nonlogical symbols match the type of *Q*. So for a *Q* of type $\langle 2,1,1 \rangle$ to be definable in *L* there must exist an *L*-sentence with nonlogical symbols P_1, P_2, and P_3, with P_1 binary and P_2, P_3 unary, which is logically equivalent to $Qxy, z, u(P_1xy, P_2z, P_3u)$. We have FO $(Q_1, \ldots, Q_n) \leq L$ if and only if each Q_i is definable in *L*.

The number of non-equivalent logics of the form FO(*Q*) is still uncountable, for each type of *Q*. Moreover, the types yield a strict hierarchy of expressive power. Types can be compared with respect to the largest degree of the relation arguments. For example, $\langle 2,1,1,3,3 \rangle$ is lower than $\langle 2,4 \rangle$. A more fine-grained (partial) order also takes into account the number of arguments of each degree. Then $\langle 3,1,2,3 \rangle$ is lower than $\langle 2,1,1,3,3 \rangle$ since it has fewer unary arguments but the same number of binary and ternary arguments. It can be proved that in each type there are quantifiers not definable in any logic FO($Q_1, \ldots, Q_n$) with $Q_1, \ldots, Q_n$ of lower types (in the more fine-grained order). Again this holds even if only finite models are considered.

The study of quantifiers in mathematical logic has either been in the direction of abstract model theory or focused on logics with particular quantifiers (and theories formulated in such logics), a prominent case being FO(Q_1) and certain of its extensions. Quantifiers have also found applications outside mathematics. Restricted to finite models, they have turned up in computer science, in attempts to find extensions of FO 'capturing' certain complexity classes from the theory of computational complexity. They have been applied to modal logic, and to the study of conditionals. But perhaps the most striking application concerns the semantics of natural languages, to which we now turn.

3 Quantifiers and natural language

Consider the following sentence form, common to many languages.



The sentence (S) consists of a noun phrase (NP) and a verb phrase (VP), and the NP in turn consists of a determiner (Det) and a noun (N). A simple English example is

(2) No student smokes

but Det, N and VP could be complex expressions. Now, given a universe *M*, N typically denotes a subset *A* of *M*, and VP another subset, *B*. Thus, Det is most straightforwardly taken to denote a binary relation between subsets of *M*, that is, a type $\langle 1,1\rangle$ quantifier on *M*. Varying *M*, Det denotes a global type $\langle 1,1\rangle$ quantifier.

In (2), this quantifier is $no_M AB \Leftrightarrow A\cap B=\emptyset$. Other Dets denote other quantifiers:

$$\begin{aligned} all_M AB &\Leftrightarrow A\subseteq B\\ at\ least\ five_M AB &\Leftrightarrow |A\cap B|\geq 5\\ most_M AB &\Leftrightarrow |A\cap B|>|A-B|\\ all\ but\ three_M AB &\Leftrightarrow |A-B|=3\\ more\ than\ two\text{-}thirds\ of\ the_M AB &\Leftrightarrow |A\subseteq B|>\tfrac{2}{3}|A|\\ all\ldots except\ John_M AB &\Leftrightarrow A-B=\{j\} \end{aligned}$$

The last example comes from a ‘discontinuous’ Det, as in, for example, ‘All students except John smoke’. A few Dets take more than one noun argument, as in

More students than teachers smoke,

which involves the type $\langle 1,1,1\rangle$ quantifier ‘more…than’ mentioned in §1.

Furthermore, NPs naturally denote type $\langle 1\rangle$ quantifiers: ‘at least five students’ denotes the set of subsets of *M* containing at least five students. In general one obtains such NP denotations from Det denotations by fixing a particular noun. Also NPs without Dets, such as ‘John’, or ‘Bill and Sue’, may be taken to denote type $\langle 1\rangle$ quantifiers:

$$\begin{aligned} &John_M B \Leftrightarrow j\in B\\ &Bill\ and\ Sue_M B \Leftrightarrow b\in B\ \&\ s\in B \end{aligned}$$

This treatment of proper names may seem complex, but has the advantage of allowing all NPs to be interpreted in the same way.

Thus, generalized quantifiers appear in a linguistic context not by means of some technical trick or invention, but rather as the most straightforward way to treat the semantics of noun phrases.

Still, is it really necessary to bring in generalized quantifiers here? After all, ‘all’ can be defined in FO by $\forall x(Ax\rightarrow Bx)$ and, similarly, quantifiers such as ‘at least five’. Nevertheless, sticking to FO is not advisable. First, the use of type $\langle 1,1\rangle$ quantifiers respects the syntactic form of sentences whereas a translation into FO does not. So generalized quantifiers facilitate a compositional semantics for natural language (see Compositionality). Second, in important cases a translation into FO is simply impossible. For example, proportional quantifiers such as ‘most’ or ‘more than two thirds of the’ are undefinable in FO. That is, there is no sentence in first-order logic, however complex, which adequately accounts for the truth-conditions of, say, ‘Most students smoke’. In fact, one can even prove that there is no such sentence in any logic FO($Q_1,\ldots,Q_n$) with $Q_1,\ldots,Q_n$ of type $\langle 1\rangle$. So type $\langle 1,1\rangle$ quantifiers are crucial also with respect to expressive power.

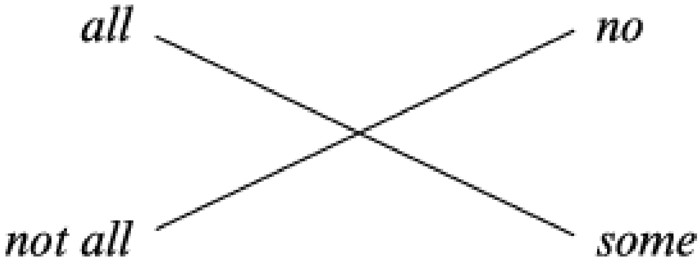
Most Dets have ISOM denotations, with putative exceptions including ‘every…but John’ or ‘John’s’. If ‘John’ denotes a fixed individual ISOM will fail, but there are various strategies for avoiding such Dets. The salient property of Det denotations, however, is the special role played by the first argument, coming from the noun: it restricts the domain of quantification. Formally this is reflected in two constraints, called ‘conservativity’ and ‘extension’: for all *M*, $A,B\subseteq M$ and $M\subseteq M'$,

$$\begin{aligned} &\text{CONS}\quad Q_M AB \Leftrightarrow Q_M A\ A\cap B\\ &\text{EXT}\quad Q_M AB \Leftrightarrow Q_{M'} AB \end{aligned}$$

CONS says that only that part of the verb argument matters which is common to the noun argument. Indeed, ‘All but three students smoke’ is equivalent to ‘All but three students are students which smoke’. CONS predicts, for example, that the Härtig quantifier $rmI_M AB \Leftrightarrow |A| = |B|$ (for which CONS fails) is not the denotation of any Det. EXT implies that the rest of the universe - the part lying outside the noun denotation - is irrelevant. It predicts, for example, that there can be no Det meaning ‘some’ on universes with, say, fewer than ten elements, and meaning ‘most’ on other universes.

Discounting a few marginal (and debatable) exceptions, all Det denotations appear to satisfy CONS and EXT. Other properties single out subclasses of quantifiers. Call *Q* ‘intersective’ if only the intersection of the noun and the verb argument matters; $A \cap B = A' \cap B'$ implies $Q_M AB \Leftrightarrow Q_M A'B'$. Examples are ‘some’, ‘at least five’, ‘exactly three’ and ‘only finitely many’. This turns out to be related to the acceptability of the corresponding Dets in ‘there’-constructions: ‘There are some/at least five/no cows in the barn’ is fine, but ‘There are all but five/most/all cows in the barn’, with non-intersective Dets, is not.

Monotonicity properties are also significant. *Q* is ‘right monotone increasing’ (or decreasing) if $Q_M AB$ and $B \subseteq B'$ (or $B' \subseteq B$) implies $Q_M AB'$. Similarly for monotonicity in the left argument. Many Dets denote right monotone quantifiers. For example, ‘more than two thirds of the’ is right monotone increasing, and ‘at most one third of the’ is right monotone decreasing (neither is left monotone). And many non-monotone cases, such as ‘(exactly) five’, ‘between three and five’ and ‘ten per cent of’, are conjunctions of a decreasing and an increasing quantifier. Right monotonicity has been related to various linguistic phenomena, in particular so-called ‘negative polarity items’. Left monotonicity is more scarce among Det denotations. It may be shown that, over finite models and assuming CONS and EXT, all left monotone quantifiers are first-order definable. Left monotone Det denotations are usually also right monotone. The four possible kinds of ‘double monotonicity’ are exemplified in the Aristotelian square of opposition:



Indeed, given CONS and a certain uniformity requirement, it can be proved that these are the *only* doubly monotone quantifiers (without this requirement there are other examples: ‘at most ten’, ‘all but at most three’, ‘infinitely many’).

NP and Det denotations are normally monadic: they relate sets. But sentences can combine several NPs with a transitive verb:

(3) Most students know at least three teachers.

The truth-conditions of (3) are an *iteration* of the two type $\langle 1, 1 \rangle$ quantifiers involved: formally (with *A* the set of students, *B* the set of teachers and *R* the relation of knowing), $most_M A\{a\ at\ least\ three_M B\{b\ Rab\}\}$. However, other seemingly similar sentences combine the quantifiers differently, for example:

(4) 1,200 philosophers wrote 2,000 entries for the Encyclopedia,

which does *not* mean that each of the 1,200 philosophers wrote 2,000 entries, as an iterated reading would have it, but rather that each of them wrote *some* entry, and that each of the 2,000 entries was written by *some* one (or more) of them. This mode of combination has been called ‘cumulation’. Another suggested mode is ‘branching’:

(5) Most of the students and most of the teachers all know each other

appears to have the reading that there is a large subset *X* of the set of students (containing more than half of them) and a large subset *Y* of the set of teachers such that every student in *X* and every teacher in *Y* know each other. Again this is not an iterated reading. But note that (3), (4) and (5) can be accounted for by quantifiers of type

$\langle 1, 1, 2 \rangle$, taking two set arguments from the nouns and one relation argument from the verb. For (3) and (4) this quantifier is definable from the monadic Det denotations, but not so for (5). More precisely, it can be shown that the branching of ‘most’ as in (5) is not definable in FO/(‘most’). Examples like this indicate a possible use also for polyadic (non-monadic) quantifiers in the semantics of natural languages.

Quantifiers, substitutional and objectual

Understood substitutionally, 'Something is F' is true provided one of its substitution instances (a sentence of the form 'a is F') is true. This contrasts with the objectual understanding, on which it is true provided 'is F' is true of some object in the domain of the quantifier. Substitutional quantifications have quite different truth-conditions from objectual ones. For instance, 'Something is a mythological animal' is true if understood substitutionally, since the substitution instance 'Pegasus is a mythological animal' is true. But understood objectually, the sentence is not true, since there are no mythological creatures to make up a domain for the quantifier.

Since substitutional quantifiers do not need domains over which they range, it is easy to introduce substitutional quantifiers which bind predicate or sentential variables, even variables within quotation marks. One reason for interest in substitutional quantification is the hope that it may provide a way to understand discourse which appears to be about numbers, properties, propositions and other 'troublesome' sorts of entities as being free of exceptional ontological commitments. Whether natural language quantification is sometimes plausibly construed as substitutional is not, however, clear.

1 Objectual and substitutional quantification

The existential quantification

(1) $\exists x\ x$ is a logician

is true if '*x* is a logician' is true in at least one case; the universal quantification

(2) $\forall x\ x$ is a logician

is true if '*x* is a logician' is true in every case. Two accounts may be given of what it is for '*x* is a logician' to be true for some or all cases. These yield two kinds of quantification: 'objectual' and 'substitutional'.

In an objectual account, the quantifier has a domain of objects; sentences such as '*x* is a logician' are related to the contents of the quantifier's domain by the 'true of' relation. The sentence '*x* is a logician' is true of a member of the domain if and only if that member is a logician; '*x* taught *y*' is true of a pair $\langle u, v\rangle$ drawn from the domain just in case *u* taught *v*, and so on. Understood objectually, (1) is true if '*x* is a logician' is true of at least one thing in the domain; (2) is true if '*x* is a logician' is true of everything in the domain.

An objectual quantifier is tied directly to the domain of objects over which it quantifies. A substitutional quantifier does not have a domain; it is not a device whose semantics is explained in terms of the 'true of' relation. Instead, a substitutional quantifier has a 'substitution class', a collection of expressions which may be substituted for the variables the substitutional quantifier binds. The 'substitution instances' of a quantified sentence such as (1) or (2) are the results of removing the initial quantifier and replacing what is bound with some member of the substitution class. For instance, if the substitution class consists of the names 'Frege' and 'Russell' (the names, not the people), the substitution instances of (1) and (2) are the sentences

Frege is a logician.
Russell is a logician.

In substitutional quantification the cases to be considered are substitution instances. Read substitutionally, (1) is true provided at least one of its substitution instances is true; (2) is true provided they all are.

In order to avoid confusion, it is best to use distinct notations for the two kinds of quantifiers. Hereafter '$\exists$' and '$\forall$' are the objectual quantifiers, '*x*' and '*y*' their variables; 'Σ' is the substitutional existential, 'Π' the substitutional universal quantifier, and '*X*' and '*S*' their variables.

How different are $\exists x\phi x$ and $\Sigma X\phi X$? Suppose the domain of '$\exists$' contains things not named by anything in the substitution class of 'Σ'. For example, say the domain of '$\exists$' is the set of all animals, and let the substitution class for 'Σ' be the proper names of animals. Not every horse has a name (proper or otherwise), so '$\exists x\ x$ is a horse and *x* has no name' is true. But '$\Sigma X\ X$ is a horse and *X* has no name' is false. If it were true, then

α is a horse and α has no name,

where α is a proper name of a horse, would be true. But if α names something, then ‘ α has no name’ is clearly false.

Another difference arises because there can (apparently) be true sentences containing empty (non-referring) names, such as ‘Pegasus is only a mythological animal’. If the animal name ‘Pegasus’ does not name anything, *a fortiori* it does not name anything in the domain of an objectual quantifier. So, if the domain of ‘ $\exists$’ is all animals, the sentence ‘ $\exists x$ x is only a mythological animal’ is false: there is not any animal which is only mythological. But the sentence ‘ ΣX X is only a mythological animal’ is true, as one of its substitution instances is true.

The quantifiers of (1) and (2) are ‘nominal’ quantifiers - their variables occupy only the positions of names or singular terms. To further appreciate the difference between substitutional and objectual quantifiers, let us consider how we might introduce *non*-nominal quantifiers into a language. To introduce a substitutional quantifier whose variables can occupy, say, the positions of predicates or whole sentences, all one needs to do is to specify a substitution class, add new variables and define ‘substitution instance’. For example, if we take expressions such as ‘is Greek’ to comprise the substitution class, we can introduce a substitutional quantifier which, like that of

(1′) ΣX (Socrates *X* and Plato *X*),

binds predicate variables. (Examples of substitution instances thereof would be ‘Socrates is wise and Plato is wise’ and ‘Socrates snores and Plato snores’.) If sentences make up the substitution class, we can write, for example,

(2′) ΠS (Dick said that $S \rightarrow$ it is false that *S*),

with a quantifier binding sentential variables. The truth-conditions of these sentences are exactly as before: (1′) is true provided at least one substitution instance is true; (2′) is true provided all are. Provided all the instances already had truth-values, such substitutional quantifications automatically have truth-values.

To introduce objectual quantifiers whose variables can occupy the positions of predicates or sentences requires one to assign domains to such quantifiers and to explain what it is for something such as ‘Socrates *X*’ or ‘Dick said that *X*’ to be true of something in the domain of the quantifier. One can do this only if there are objects to make up the domain. Since appropriate domains for predicate and sentential variables seem to be, respectively, sets (or, perhaps, universals) and propositions, someone with doubts about their existence ought to have doubts about the objectual analogues of (1′) and (2′) (see Nominalism §4). No such worries attach to (1′) and (2′) themselves.

Some have hoped that substitutional quantification would provide an innocuous means of interpreting non-nominal natural language quantifications, such as ‘Bill did all that John did’ and ‘There’s something Socrates is that Plato is too’. Some hope it will interpret apparently nominal quantifications (‘Whatever Dick said is false’) and numerical quantification, whose domains seem to some ontologically suspect.

Another reason for interest in substitutional quantification is worries about the coherence of using an objectual quantifier to ‘quantify into’ positions like that occupied by ‘Jane’ in

It is possible that Jane is happy.
Nancy thinks that Jane is happy.

The position of ‘Jane’ in these sentences is ‘opaque’ (it is a position for which substitution of terms which pick out the same thing can lead from truth to falsehood; see Propositional attitude statements §2; Modal logic, philosophical issues in §3). Quine has argued repeatedly that an objectual quantifier cannot bind a variable in opaque position (see Quine 1951). Now, many perfectly good English sentences, for example,

(3) Some unhappy woman could have been happy.
There’s someone [such that] Nancy thinks [that she] is happy.

seem to involve quantification into opaque position. Since there is no problem with a substitutional quantifier binding a variable in opaque position, one might conclude that sentences such as in (3) involve substitutional quantification.

In the author's opinion, it is implausible that English quantification into opaque positions as in (3) can or should be interpreted substitutionally. For one thing, Quine's arguments that an objectual quantifier cannot bind a variable in opaque position are unsound (see Kaplan 1986). Furthermore, the way we mix quantifiers and expressions such as 'believes' prohibits a substitutional reading of the quantifier. Consider

(4) Twain is Clemens; Sal believes that Twain is sad; Sal does not believe that Clemens is sad.

This does not imply

(5) Twain is something such that Sal believes that it is sad and Twain is something such that Sal does not believe that it is sad,

since (4) could be true, but (5) ascribes contradictory properties to Twain. Now (5) seems to have the form

(6) (Ex)($x =$ Twain & Sal believes that x is sad) &
(Ex)($x =$ Twain & Sal does not believe that x is sad).

If the existential quantifier 'E' in (6) is objectual, (4) does not imply (6), since no object in the domain could make both conjuncts true. But if it is substitutional, (4) does imply (6), and hence (5). But we have already said that (4) does not imply (5). So the quantifier is not substitutional. (Incidentally, this shows that when a substitutional quantifier binds variables in opaque positions, $\exists x \phi x$ and $\Sigma X \phi X$ may have different truth-values even if the substitution class for ' Σ' consists only of names of objects in the domain of ' $\exists$', and every such object is named by a member of the class.)

The above is not meant to suggest that one cannot substitutionally quantify into opaque positions, but only that English quantification into such positions is not substitutional. In fact, substitutional quantifiers are very useful when one wants to bind variables in positions, such as those inside quotation marks, where it is indeed impossible in English to bind a referential variable. A formula along the lines of

(7) ΠS: 'S' is true if and only if S

is perfectly intelligible, and may even, in certain cases, be looked upon as 'defining truth' (see Kripke 1976 and Grover 1992 for discussion).

2 Interpreting natural language quantifiers

Natural language quantifiers cannot in general be plausibly understood as substitutional. Is quantification in English (or other natural languages; the disjunct is dropped hereafter) ever plausibly taken to be substitutional? If so, what, if anything, might this say about the 'ontological commitments' of speakers?

Some philosophers (Gottlieb, for example) have suggested that English quantifiers are ambiguous, between substitutional and objectual ones. Others (Marcus 1993, for example) have suggested that substitutional quantifiers provide, in some sense, the primary interpretation of English idioms of quantification, the objectual interpretation being a limiting or special case.

Arguments for the ambiguity thesis often turn on intuitions about what (the use of) a sentence ontologically commits one to. Roughly speaking, a sentence *S* ontologically commits one to there being an *F* provided that, as a matter of logic, one cannot consistently hold that *S* is true but there is not an *F*. (More precisely, let *F* be a singular English noun and let *s* name the English sentence *S*. '*s* ontologically commits one to there being an *F*' is true if the sentence 'If *S*, then there is an *F*' is logically true, when 'there is' is understood objectually. To say '*s* commits one to *a*' is to say that '*a* exists' follows from *S*. See Ontological commitment.)

One particular argument for the ambiguity thesis runs as follows: 'Quine believes that there are no propositions' is true; and 'If Quine believes that there are no propositions, then there is a thing Quine believes' is a logical truth, and thus a truth. So 'There is a thing Quine believes' is true. But Quine is not ontologically committed to the existence of things believed (propositions) since he says that he does not think there are any. So in English 'there is' is not always an objectual quantifier. So, presumably, it is sometimes a substitutional one. Another argument observes that to explain why

(8) If there are exactly as many boys as girls, then if there are 5 boys, there are 5 girls

is logically true, one must interpret its antecedent as involving numerical quantification; but asserting its antecedent surely does not commit one to the existence of numbers (see Gottlieb 1980). The arguments depend on the neutrality thesis: a substitutional quantification ΣXFX does not commit one to there being an *F* if none of its instances do. Given the definition of ontological commitment, the neutrality thesis is trivially true, since any substitution instance of ΣXFX logically implies it.

Such arguments must be evaluated on a case-by-case basis. As for the first, one might simply note that existential generalization (the move from something whose syntactic form is '*a* is *F*' to 'Something is *F*') is not valid without restriction. The second argument seems inconclusive, at least given that what is at issue is the commitments of one who embraces the range of quantitative inferences commonly held valid in English, and accepts arithmetic practice as well as standard use of numerical talk for measurement, counting, estimating, and so on.

Even if the evidence for the ambiguity thesis is at best equivocal, the project of attempting to see how much of a stretch of a discourse (about, say, numbers, or properties, or propositions) can be interpreted substitutionally is often of interest. Even if we are most plausibly understood to be committed to existence of a sort, we might welcome the news that we need not be. In evaluating the claim that a stretch of discourse can be interpreted substitutionally, one needs to consider several questions.

First, how satisfactory is the account provided of the truth of substitution instances? If 'Some numbers are prime' is substitutional, the truth of '7 is prime' is not explained by saying that 'is prime' is true of 7. We then need an account of what makes '7 is prime' true but '8 is prime' false.

Second, how much apparently true discourse does a substitutional account render problematic or false? It is not altogether clear how much conventional mathematics can be accepted when its quantifiers are read substitutionally. (For one thing, substitutional quantification seems to require limits on expressibility akin to those in predicative logic.) It is not clear how a substitutional interpretation of 'Katya said something' can explain its truth as a report of Katya's assertive utterance of a sentence untranslatable into English. (One could say that some set theory or talk of Katya's assertions is false but useful fiction.)

Third, to what extent do the terms of a substitutional account undercut its motivation? For nominalists, substitutional quantification is of interest because it may offer a way to re-interpret a theory (without requiring significant change in the way it is used) so that it can be adopted by the ontologically scrupulous. Such nominalists need to be careful about what they themselves (objectually) quantify over, in giving a substitutional account of a theory. For example, the natural understanding of the substitution class for 'Π' for a language for arithmetic will identify it with an infinite set of expression 'types'; to give an adequate substitutional account of a language as strong as second-order arithmetic seems to require quantifying over sequences. But types and sequences are not objects acceptable to most nominalists (see Parsons 1971 and 1982).

Quine has claimed that substitutional quantification is irrelevant to questions of ontology, saying that 'the question of the ontological commitment of a theory does not properly arise' (1969) unless the theory is formulated in an objectual first-order language or translated into such. But surely this is not so. If quantifier-free expressions of English number theory do not in fact contain names of numbers, and English numerical quantification is substitutional, then English numerical discourse is free of commitment to numbers. In fact, if this is so, it is presumably untranslatable into objectual idiom, since such translation would involve wrongly ascribing such commitment.

3 Logic and semantics

There are many interesting issues in the logic and semantics of substitutional languages. The reader is directed to Kripke, Parsons and Grover for a sampling. Here we confine ourselves to mention of two fundamental facts about substitutional languages.

First, $\Sigma X\phi X$ is true provided one of its substitution instances is. Thus, if one is to define truth inductively for a language in which substitutional quantifiers occur, with the definition assigning a truth-value to every sentence, the substitution class for the quantifiers cannot contain expressions in which those very quantifiers are used.

Kripke suggests that it is best to think of substitutional quantifiers as being introduced by extending a given (interpreted) language to a new language. The extension is achieved by introducing new variables for the quantifiers, defining a substitution class *C* thereof (consisting of some expressions of the original language) and taking the atomic sentences of the new language to be all the sentences of the old language along with results of replacing members of *C* in the base language with variables. (Call the last, following Kripke, 'forms'. Strictly, forms are those results, of replacing members of *C* with variables, which always return a sentence of the base language when the new variables are replaced with members of *C*.) As Kripke (and, earlier, Marcus) observe, provided the quantifiers are introduced in this way, one can formulate 'truth-definitions' along the lines of (7) without paradox.

Second, in the case of first-order languages (without identity), choosing between objectual and substitutional quantifiers need not affect what we say about validity or satisfiability. (Again we rely on Kripke's work.) Consider the first-order substitutional and first-order objectual predicate calculi, which differ only in their quantifiers and variables. Think of an interpretation of the substitutional calculus (SC) as being given by specifying an interpreted language *L* and (non-empty) substitution class *C* therein, assigning members of *C* to SC's constants, forms (of appropriate number of argument places) of *L* to the predicate letters of SC. If validity for SC is truth in any such interpretation, and validity for the objectual predicate calculus is truth in any (objectual) interpretation, then a sentence of SC is valid if and only if its objectual analogue (the result of trading substitutional quantifiers and variables for objectual ones) is.

Quantum logic

The topic of quantum logic was introduced by Birkhoff and von Neumann (1936), who described the formal properties of a certain algebraic system associated with quantum theory. To avoid begging questions, it is convenient to use the term 'logic' broadly enough to cover any algebraic system with formal characteristics similar to the standard sentential calculus. In that sense it is uncontroversial that there is a logic of experimental questions (for example, 'Is the particle in region R?' or 'Do the particles have opposite spins?') associated with any physical system. Having introduced this logic for quantum theory, we may ask how it differs from the standard sentential calculus, the logic for the experimental questions in classical mechanics. The most notable difference is that the distributive laws fail, being replaced by a weaker law known as orthomodularity.

All this can be discussed without deciding whether quantum logic is a genuine logic, in the sense of a system of deduction. Putnam argued that quantum logic was indeed a genuine logic, because taking it as such solved various problems, notably that of reconciling the wave-like character of a beam of, say, electrons, as it passes through two slits, with the thesis that the electrons in the beam go through one or other of the two slits. If Putnam's argument succeeds this would be a remarkable case of the empirical defeat of logical intuitions. Subsequent discussion, however, seems to have undermined his claim.

1 The logic of experimental questions

Idealizing physics somewhat, we can think of repeatable experiments as types of observation and the results as values of the corresponding observable. Given any set of possible results, *R*, for a type of observable, *O*, there is an experimental question, namely: 'Will the observation of *O* produce a value in the set *R*?'

If experiments are repeatable, then there must be some significance to the results of repeating them on systems in - idealizing again - the same state. For theories such as classical mechanics and quantum theory, therefore, we may take the statistics resulting from repetition to be manifestations of probabilities. In our idealized treatment, we then assign a precise numerical probability $u(a)$ to the 'yes' result for a given experimental question *a* when asked of a system in a state *u*. This connection between experimental questions and states imposes a logic on the experimental questions.

First we say that two experimental questions are 'equivalent' if they are assigned the same probability by every state. It is then convenient to talk as if equivalent experimental questions were identical. Next we define an entailment-like partial ordering, '$\leq$', on experimental questions: $a \leq b$ if, for all states *u*, $u(a) \leq u(b)$. The intuitive idea is that if *a* fails to 'entail' *b* then there is some state in which a 'yes' answer for *a* is more probable than a 'yes' for *b*. We define a maximum element 1 and a minimum element 0 corresponding to the trivial experimental questions which always give a 'yes' answer, or a 'no' answer, respectively. Moreover, there is a negation-like complement operator, where $a^{\perp}$, the complement of *a*, has a 'yes' answer precisely when *a* has a 'no' answer. Hence $(a^{\perp})^{\perp} = a$ for any experimental question *a*. Also for any experimental question *a* and any state *u*, $u(a) + u(a^{\perp}) = 1$. From this it follows that the logic is 'orthocomplemented', that is, $a \leq b$ implies $b^{\perp} \leq a^{\perp}$. We may then define the 'orthogonality' relation $a \perp b$ ('*a* is orthogonal to *b*') to hold if $a \leq b^{\perp}$, or, equivalently, $b \leq a^{\perp}$. In standard logic two propositions are 'inconsistent' just in case one entails the negation of the other. Orthogonality is the analogue of inconsistency.

The 'meet' $a \wedge b$, if it exists, is the greatest (with respect to '$\leq$') experimental question less than or equal to both *a* and *b*. It is analogous to the conjunction $p \,\&\, q$ of two propositions, which is the meet with respect to the ordering of entailment. Likewise the 'join' $a \vee b$, if it exists, is the least experimental question greater than or equal to both *a* and *b*. It is analogous to the disjunction, $p \text{ or } q$ of two propositions, which is the join with respect to the ordering of entailment. Because the logic is orthocomplemented, De Morgan's laws hold.

$$(a \wedge b)^{\perp} = a^{\perp} \vee b^{\perp}$$
$$(a \vee b)^{\perp} = a^{\perp} \wedge b^{\perp}$$

Thus far we have been exploring a priori the consequences of characterizing physics as having to do with idealized repeatable experiments on systems. The logic of experimental questions may be further developed by means of a

constraint which, although inspired by quantum theory and not merely the result of conceptual analysis, seems antecedently plausible. This is ‘postulate M’: given any pairwise orthogonal set of experimental questions $\{a_i\}$ there is an experimental question *b* such that, for any state *u*, $u(b)+u(a_1)+u(a_2)+\ldots=1$ (see Hughes 1989: 198). This is plausible because it amounts to there being an experimental question *b* which has the ‘yes’ answer just in case all the a_i have the ‘no’ answer. It may be inferred from postulate M by the Mackey-Maczynski theorem that the logic of experimental questions is ‘orthomodular’ (see Hughes 1989: 198), a weakened form of ‘distributive’. That is, every pairwise orthogonal countable subset has a join and the orthomodular property holds: for any experimental questions *a* and *b* such that $a \leq b$, $b = a \vee (b \wedge a^{\perp})$.

We might expect the analogue of the material conditional, $(\text{not-}p)$ or q, to be $a^{\perp} \vee b$, but since the material conditional could also be characterized as $(\text{not-}p)$ or $(p$ and $q)$, another analogue is $a^{\perp} \vee (a \wedge b)$, which I abbreviate to $a \rightarrow b$. In fact it is the latter which is appropriate, because we require the analogue of *modus ponens*, namely $a \wedge (a \rightarrow b) \leq b$ (see Gibbins 1987: 139). The orthomodular property may then be stated succinctly: for any experimental questions *a* and *b* such that $a \leq b$, $b = a^{\perp} \rightarrow b$.

2 The nonclassical character of quantum logic

It is plausible, then, but not the result of pure conceptual analysis, that the logic of experimental questions forms an orthomodular partially ordered set.

For classical physics this logic is in addition a distributive lattice and so a Boolean algebra. (To say it is ‘distributive’ is to say that the familiar distributive laws hold.

$$a \wedge (b \vee c) = (a \wedge b) \vee (a \wedge c)$$
$$a \vee (b \wedge c) = (a \vee b) \wedge (a \vee c)$$

To say it is a ‘lattice’ is to say that every pair of experimental questions has a join and a meet.) The logic of experimental questions for quantum theory is not, however, a Boolean algebra. Instead it is usually taken to be isomorphic to an orthocomplemented partially ordered set which occurs naturally in an infinite-dimensional Hilbert space.

Without loss of generality we may think of a vector v in this Hilbert space as an infinite sequence of (complex) numbers $\langle v_1, v_2, v_3, \ldots\rangle$. Given numbers *s* and *t*, we can form the linear combination $\mathbf{z} = s\mathbf{v} + t\mathbf{w}$ of vectors v and w, with $z_i = sv_i + tw_i$ for all *i*. More generally, given any set *e* of vectors we can consider those vectors which are finite or infinite linear combinations of members of *e*. This is the (closed) ‘span’ of *e*, which we shall write as ‘ $[e]$’. (That it is closed with respect to the appropriate topology follows from the inclusion of infinite linear combinations.) A (closed) linear subspace is then any non-empty set *a* of vectors such that $[a] = a$.

These vectors are analogues of coordinate triples in three-dimensional Euclidean space. In this example, the linear subspaces, which are all closed, comprise (1) the coordinates of the origin, O, (2) lines through O, (3) planes through O, and (4) the whole of space. (1) and (4) correspond, respectively, to the elements 0 and 1 in the lattice, which is ordered by inclusion. So, for instance, if *a* is the set of coordinates for a line through O and *b* for a plane through O, then $a \leq b$ just in case the line is in the plane. The meet of two members of the lattice of closed linear subspaces is just their intersection. The join is not, however, the union, for the union is not in general a linear subspace (for example, the union of two lines is not a plane). Instead, the join is the *span* of the union (for instance, the set of coordinates of the plane containing the two lines).

Now some pairs of vectors in Hilbert space are orthogonal. This enables us to define the ‘orthogonal complement’ $e^{\perp}$ of a set of vectors *e* as the set of all vectors orthogonal to all vectors in *e*. This provides an alternative characterization of the span as $[e] = (e^{\perp})^{\perp}$. Hence if *a* is a closed linear subspace, then $(a^{\perp})^{\perp} = a$.

The lattice of closed linear subspaces of a Hilbert space is not a Boolean algebra, for the distributive laws fail to hold. The reason for this is easily seen in the case of the coordinate triples. Consider three different sets of coordinate triples *a*, *b* and *c* corresponding to three lines OA, OB and OC all in the one plane. Then $b \vee c$ corresponds to the plane they lie in, so $a = a \wedge (b \vee c)$. But $a \wedge b$ is the intersection of *a* and *b* and is therefore $\{\langle 0,0,0\rangle\}$. Hence $a \wedge b = 0$. Likewise $a \wedge c = 0$. So $(a \wedge b) \vee (a \wedge c) = 0 \vee 0 = 0$. The orthomodular law, a weakening of the distributive laws, does hold.

The claim that quantum logic is a lattice could be justified either by the convenience of the standard representation using closed linear subspaces of a Hilbert space, or on the basis that we should depart as little as possible from the classical case. It is not, however, easy to find any other reasons (see Hughes 1989: 200).

The nonclassical character of quantum logic is also exhibited by its valuations. Consider the following weakening of the requirements for a valuation of the standard sentential calculus: $\mathrm{Val}(1) = 1$ and if $a \perp b$ then $\mathrm{Val}(a \vee b) = \mathrm{Val}(a) + \mathrm{Val}(b)$, from which it follows that $\mathrm{Val}(0) = 0$. Any (pure or mixed) quantum state may be thought of as such a valuation with $\mathrm{Val}(a)$ being the probability assigned by the state to the experimental question *a*. It can be shown that such a valuation must take all the values between 0 and 1. (In particular, there is no two-valued or three-valued valuation. That there is no two-valued valuation is Kochen and Specker's theorem.) Following Kochen and Specker, consider a spin 1 system in which the spin component in any direction takes the values -1, 0 and $+1$ (see Kochen and Specker 1967; Hughes 1989: 164-70). So for any direction *p* we have the experimental question o_p which has the 'yes' answer just in case the spin component in that direction is 0. For any three orthogonal *p*, *q* and *r* directions, the triad o_p, o_q and o_r are pairwise orthogonal experimental questions and their join is 1. Hence we would have $\mathrm{Val}(o_p) + \mathrm{Val}(o_q) + \mathrm{Val}(o_r) = 1$. Gleason's theorem then tells us that $\mathrm{Val}(o_p)$ is a quadratic function of the coordinates of *p*. Hence it is continuous and takes all values between the minimum, 0, and the maximum, 1.

3 An alternative approach to quantum logic

The presentation so far has been in the tradition of the paper by Birkhoff and von Neumann (1936) and the work of Mackey (1963). But there is an alternative approach to quantum logic due to Kochen and Specker (1965). The idea is to think of the logic as a family $\{B_i\}$ of overlapping Boolean algebras, each, intuitively, consisting of a family of experimental questions which can be answered without interfering with each other. We require the B_i to share the same maximum and minimum elements 0 and 1 (the two trivial questions) and to be such that the operations '$\wedge_i$', '$\vee_i$' and '$\perp_i$' agree on the overlaps. The family $\{B_i\}$ is called a 'partial Boolean algebra' if a 'coherence condition' holds. Call members of the logic 'neighbours' if there is some B_i to which they all belong. Coherence then says that if *a*, *b* and *c* are pairwise neighbours then they are neighbours. The set of closed linear subspaces of a Hilbert space is a partial Boolean algebra in which the Boolean subalgebras consist of sets of subspaces which make angles of either $0°$ or $90°$ with each other. For the case of the lattice of coordinate triples, each Boolean subalgebra contains eight members and is specified by a choice of three perpendicular lines OP, OQ and OR through O. The subalgebra then consists of the coordinate sets for (1) the origin, O, (2) the lines OP, OQ and OR (3) the planes OQR, ORP and OPQ, and (4) the whole of three-dimensional space (see Hughes 1989: 192-4).

The natural way of defining a valuation for a partial Boolean algebra would be one which satisfied the usual truth-functional constraints on each Boolean subalgebra. But such a valuation would have to satisfy the constraint that $\mathrm{Val}(1) = 1$ and that if $a \perp b$ then $\mathrm{Val}(a \vee b) = \mathrm{Val}(a) + \mathrm{Val}(b)$. As we have seen, such valuations must take all values between 0 and 1.

4 The logical reformulation of quantum theory

The fact that one important difference between quantum and classical physics can be expressed as a purely algebraic difference in the corresponding logics has inspired the programme of formulating quantum theory in terms of its logic of experimental questions. There is no obstacle to this provided the logic is assumed to be that of the closed linear subspaces of a Hilbert space. Given that assumption, the first step is to classify the states, which are identified with the probability measures on the logic. Assuming postulate M (see §1 above) this amounts merely to taking the states to be valuations which assign values in the range 0 to 1. Gleason's theorem tells us that, for any Hilbert space of dimension greater than two, the states thus characterized are all the mixtures (in positive proportions adding up to 100 per cent) of the standard pure states of quantum theory, which correspond to vectors in the Hilbert space. (The state represented by vector v assigns to a closed linear subspace *a* the square of the cosine of the angle between v and *a*.)

The next step is to consider the dynamics by which states change over time. The results of Mackey and Kadison show that we may represent the vectors in the Hilbert space as suitable functions on ordinary (that is, three-dimensional Euclidean) space in such a way that the dynamics is given by the familiar Schrödinger equation (see Beltrametti and Cassinelli 1981: 252-4). The difficulty with the programme, however, is in providing simple

algebraic constraints which ensure that the logic of experimental questions is indeed represented by the set of closed subspaces of a Hilbert space (1981: ch. 21).

5 The status of quantum logic

What is the status of quantum logic? There seem to be three sorts of answer: the neoclassical, the quantum ontologists' and the quantum logicians'. The neoclassical answer is that quantum logic is more a mathematical curiosity than anything of great significance in understanding the physical world. Its non-Boolean character is the result of constraints on the questions it is physically possible for us human beings to answer, so that we might think of God as knowing the answers to two questions whose meet is the null question but which are not classically inconsistent (for example, the questions: 'Is the particle in bounded region *R*?' and 'Does it have momentum in bounded set *S*?'). Hence the meet, ' $\wedge$', would not be a genuine conjunction even though it has analogous properties. For that reason the partial Boolean algebra formulation might be judged more perspicuous because the ' $\wedge_i$' of a given Boolean subalgebra could be treated as a classical conjunction (see Garden 1984; Forrest 1988; Garola 1992).

The quantum ontologists' answer is that quantum logic tells us something important about the structure of the physical world, but that 'logic' is a misnomer, for it should not be interpreted as a theory of deductive reasoning. On this view the best way to describe the physical world is by specifying the 'logic' (better 'algebra') of experimental questions and specifying the states as probability measures on this logic (see §4). This is arguably implicit in the Copenhagen interpretation, and it would seem to be the position of van Fraassen (1991: ch. 5) and, in a more radical version, of Hughes (1989: ch. 10).

The quantum logicians' answer is that quantum logic holds because it is in fact the correct deductive logic for all thought, and we made a mistake in assuming classical logic, which we should abandon, not merely when considering quantum theory, but quite generally. This was Putnam's position and it has also been advocated by Stairs (see Putnam 1969; Stairs 1982).

How might we decide between these answers? While logic might well be empirically defeasible it does not seem to be initially derived from experience. Hence there is a burden of argument on the quantum logicians. Putnam (1969) took up this burden by arguing that abandoning the distributive law enables us to resolve various problems without abandoning a realist interpretation of quantum theory. If so, then indeed a case would have been made for the empirical defeat of classical logic, comparable to the empirical defeat of Euclidean geometry. Unfortunately, Putnam's claims are open to serious criticism. For example, Putnam noted that in the two-slit thought-experiment we might have expected the probability of a particle hitting the screen in a given region when both slits are open to be the mean of the two probabilities with one slit closed. But that result violates quantum theory. It seemed that we could, by rejecting distributivity, retain an interpretation in which particles really do pass through one slit or the other, without allowing action at a distance. The objection to this, made forcibly by Gibbins, is that even given quantum logic, realism about particles which pass through one rather than another slit, combined with the rejection of action at a distance, still gives us a result contrary to quantum theory, namely that the probability of a particle hitting the screen in a certain region should be at least as great as the mean of the probabilities with one slit closed. But in fact, for some regions that inequality does not hold (see Gibbins 1987: ch. 10).

If we reject the quantum logicians' answer then that of the quantum ontologists would be plausible enough, especially given the discovery of simple constraints on the logic which ensured it could be represented by the closed subspaces of a Hilbert space. Presumably, however, the choice between the neoclassical and the quantum ontologists' answers will depend on the overall advantages and disadvantages of their interpretations of quantum theory (see Quantum mechanics, interpretation of).

Quantum measurement problem

In classical mechanics a measurement process can be represented, in principle, as an interaction between two systems, a measuring instrument M *and a measured system* S*, during which the classical states of* M *and* S *evolve dynamically, according to the equations of motion of the theory, in such a way that the 'pointer' or indicator quantity of* M *becomes correlated with the measured quantity of* S. *If a similar representation is attempted in quantum mechanics, it can be shown that, for certain initial quantum states of* M *and* S*, the interaction will result in a quantum state for the combined system in which neither the pointer quantity of* M *nor the measured quantity of* S *has a determinate value. On the orthodox interpretation of the theory, propositions assigning ranges of values to these quantities are neither true nor false. Since we require that the pointer readings of* M *are determinate after a measurement, and presumably also the values of the correlated* S*-quantities measured by* M*, it appears that the orthodox interpretation cannot accommodate the dynamical representation of measurement processes. The problem of how to do so is the quantum measurement problem.*

1 States in classical and quantum mechanics

Classical mechanics describes model universes in which the state of the universe can be specified by an assignment of values to the positions and momenta of the systems in the universe, hence to all dynamical quantities, which are defined as functions of positions and momenta. The equations of motion yield rates of change for positions and momenta in terms of the Hamiltonian, a function of positions and momenta, and generate a possible history of the universe from the position and momentum values specified at some particular time. So we can understand a classical universe as consisting of separable classical systems interacting under the influence of forces encoded in the Hamiltonian. The evolution of the universe over time - a history of the universe - is given by a particular dynamical evolution of its state (see Mechanics, classical; Models).

The state of a model classical universe plays two distinct roles: a *diachronic* role as the carrier of the dynamics over time, and a *synchronic* role as the specification of a 'possible world' at a particular time; that is, the selection of a set of determinate values for the dynamical quantities as one of the possible sets of values for these quantities, equivalently the selection of a set of properties for the systems in the universe as one of the possible sets of properties.

The dynamical quantities, represented by real-valued functions on the classical state space or 'phase space' coordinated by the positions and momenta (not to be confused with real space), form a commutative algebra with respect to addition and multiplication. Properties in classical mechanics are represented by subsets of phase space (or, equivalently, by functions that take the values 1 on the subset and 0 elsewhere). The property that the value of a dynamical variable A lies in a certain range R is represented by the subset of classical states (phase space points) for which this property holds, via the functional relationship between A and positions and momenta. The properties form a Boolean algebra, isomorphic to a set of subsets of phase space. Classical states correspond to singleton subsets, minimal non-zero elements, or atoms in this algebra. The collection of properties represented by subsets of phase space containing the state is selected as the possible world associated with the state in the synchronic sense.

Quantum mechanics is derived as a generalization of classical mechanics in which certain 'canonically conjugate' quantities (like position and momentum) fail to commute with respect to multiplication. We obtain a non-commutative algebra of dynamical quantities that is representable as an algebra of operators on a Hilbert space, a linear vector space over the complex numbers. The dynamical quantities correspond to operators that can be decomposed into linear sums or integrals of projection operators, with real coefficients (the 'eigenvalues' of the operators) that represent the possible values of the quantities. Each projection operator has eigenvalues 0 and 1, and maps the Hilbert space onto a subspace that is the range of the operator. Properties are represented by subspaces or the corresponding projection operators and form a non-Boolean algebra, isomorphic to the algebra of projection operators or subspaces of Hilbert space. The one-dimensional subspaces or rays are atoms in this algebra and represent states in the diachronic sense; that is, they represent dynamical states that evolve over time according to the linear equation of motion of the theory (see Quantum logic §2).

On the *orthodox* interpretation of quantum mechanics, the rays (or unit vectors along the rays) are also taken to represent states in the synchronic sense. The collection of properties determined by a ray in Hilbert space as

obtaining in a model quantum mechanical universe is taken as the collection of subspaces containing the ray, just as the collection of properties belonging to a classical state in the synchronic sense is the collection of properties represented by subsets of phase space containing the state as a point in phase space. Properties represented by subspaces orthogonal to the ray are taken as not obtaining in the model universe, while properties represented by subspaces that are neither orthogonal to the ray nor contain the ray are regarded as indeterminate.

2 The source of the problem

The orthodox decision to take the ray representing a quantum state as defining a state in the synchronic sense has the consequence that we can no longer apply quantum mechanics to model quantum mechanical universes in the same way that classical mechanics is applied to model classical universes. In addition to selecting properties that obtain, properties that do not obtain, and properties that are indeterminate, the ray representing the quantum state is interpreted as assigning *probabilities* to *all* the properties represented by subspaces of the Hilbert space: probability 1 to properties represented by subspaces that contain the ray; probability 0 to properties represented by subspaces orthogonal to the ray; and non-zero probabilities to all other properties. These probabilities are not representable in the usual way as measures over different possible worlds, one of which is actual, defined by the orthodox interpretation of quantum states in the synchronic sense. So a non-zero probability assigned to the property that the value of a dynamical variable *A* lies in a certain range *R* is said to be ‘the probability of finding the value of the dynamical quantity in the range *R* on measurement’. This means that the application of quantum mechanics is restricted to providing probabilities for the results of measurements on model quantum mechanical universes by some agent or device *external* to these universes. To mark this distinction between classical and quantum mechanics, dynamical quantities in quantum mechanics are referred to as ‘observables’, where an observable is understood to have no determinate value unless the ray representing the quantum state lies in one of the subspaces associated with the projection operators of the observable, a circumstance that is presumed to occur when the observable is measured.

This notion of ‘measurement’ is undefined dynamically, as is the notion of an observable having no determinate value at one time and coming to have a determinate value at some other time as the outcome of a ‘measurement’. As Bell put it (1987), one would like to have an interpretation of quantum mechanics, our most fundamental theory of motion, in terms of ‘beables’ instead of ‘observables’. What we want is an *internal* account of measurement in quantum mechanics, and this appears to be excluded by the orthodox interpretation of quantum states and the linear dynamics of the theory.

To see what goes wrong with an internal account of measurement on the orthodox interpretation, consider a model quantum mechanical universe consisting of a measuring instrument *M* and a measured system *S*. Suppose that the initial quantum state of $S+M$ is such that, according to the orthodox interpretation, an observable *A* of *S* has some determinate value and a ‘pointer’ or indicator observable *R* of *M* has a determinate zero value. Then there exists a dynamical evolution that results in a final quantum state for $S+M$ in which both *A* and *R* are determinate and *R* has some non-zero value that depends on the initial value of *A*. In this case, the dynamical evolution can be taken as representing a measurement of *A* via the pointer *R* in this model universe. But now it follows from the linearity of the dynamics of the theory that if the initial quantum state of $S+M$ is a state in which *S* has no determinate *A*-value, and *R* has the determinate zero value, then the final state of $S+M$ must be a state in which both *A* and *R* are indeterminate. So the dynamical evolution cannot be taken as representing a measurement in this case.

Schrödinger (1935) pointed out that if *M* represents a cat and *R* takes two possible values, associated with the cat being alive and dead, and the cat interacts with a microsystem *S*, such as an atom that can either decay or not decay in a certain time (where these events are associated with the two possible values of *A*), the decay event triggering a device that kills the cat, then the cat will be neither alive nor dead after the measurement interaction, according to the orthodox interpretation.

3 Proposed solutions

States represented by rays in Hilbert space are referred to as ‘pure’ states in quantum mechanics. The theory also introduces ‘mixed’ states or ‘mixtures’, which can be decomposed into probability distributions over pure states and interpreted epistemically (subject to certain qualifications introduced by the nonuniqueness of this

decomposition). In terms of this distinction, the measurement problem arises because the final state of the instrument *M* and, measured system *S*, after a dynamical interaction representing a measurement, is a pure state associated with a ray that does not lie in any of the subspaces representing pointer properties of *M* or measured properties of *S*. What we appear to require after a measurement interaction is a mixed state for the combined system $S + M$, in which pure states that are determinate for different possible measurement outcomes occur with the appropriate probabilities.

There is a series of impossibility theorems by Wigner (1963), Fine (1970), Shimony (1974), and others that show, under very general constraints on what counts as a measurement interaction, that no evolution of the combined system $S + M$ governed by the linear dynamics of the theory can result in a final state for $S + M$ that is a mixture over pure states in which the pointer properties of *M* are determinate, on the orthodox interpretation of pure states.

Standard formulations of quantum mechanics invoke two modes of dynamical evolution for the pure state of a quantum system: the usual deterministic linear evolution, described by the equation of motion of the theory, that occurs when the system does not undergo measurement; and a second stochastic evolution that occurs when the system is measured and transforms the pure state into the required mixture. This measurement evolution is characterized by a 'projection postulate' as the projection or 'collapse' of the pure state onto one of the pure states in the mixture, with the appropriate probability.

Von Neumann's justification for this duality was that a measurement divides the world into two parts: the observed system and the observer (1932). We can follow all physical processes in the observed system with arbitrary precision, in principle, but not in the observer. The linear dynamics describes systems in the observed part of the world, so long as they do not interact with the observing part. When such an interaction occurs, the projection postulate applies. Consider the measurement of *S* by an instrument *M* and observer M'. The boundary between the observed system and the observer can be drawn between *S* and $M + M'$ or between $S + M$ and M'. Von Neumann showed that the application of the projection postulate directly to the system *S* is consistent with its application to the system $S + M$, after a suitable dynamical interaction between *S* and *M* governed by the linear equation of motion of the theory.

Von Neumann's argument for two distinct dynamical processes in quantum mechanics is hardly convincing, if only because classical mechanics requires no such duality. Indeed, the measurement problem is often formulated as the problem of reconciling these two modes of evolution in some way. Proposed solutions to the problem are restricted by the impossibility theorems and either (i) accept the orthodox interpretation and modify the linear dynamics of the theory; or (ii) accept the linear dynamics and modify the orthodox interpretation; or (iii) accept both the orthodox interpretation and the dynamics, and attempt to show that the difference between the mixture required by the orthodox interpretation and the pure state obtained on the basis of the linear dynamics can be ignored for all practical purposes, if certain relevant features of real measurement interactions are taken into account.

An example of a type (i) or 'collapse' proposal is the theory of Ghirardi, Rimini and Weber (1986). This theory introduces a modified dynamics for the quantum state that results in the occasional spontaneous localization of individual microsystems - so infrequently that the time evolution of a single particle follows the usual linear dynamics over long time intervals with high probability. For macrosystems, which consist of enormously large numbers of particles, the modified dynamics results in the almost instantaneous transition of pure states to mixed states for which macroscopically distinct position properties are determinate. The underlying claim is that all measurements can be characterized as ultimately involving macroscopic changes in the position of something that can function as a macroscopic pointer.

Type (ii) or 'no collapse' proposals include Bohm's hidden variable theory (1952), Everett's (1957) 'relative state' or 'many worlds' interpretation, and 'modal' interpretations, which interpret the pure quantum state as a dynamical state specifying probabilities only, and reject the orthodox interpretation in favour of alternative specifications for what collections of properties are determinate that are intended to support a purely internal account of measurement (see van Fraassen 1991).

Finally, type (iii) proposals include 'decoherence' theories and various other attempts to exploit the large number

of degrees of freedom of the amplifying recording device, or the environment of the system, as the source of a dissipative process that effectively renders a final pure state, after a measurement process, empirically indistinguishable from the required mixture. Such proposals work only if we suppose that properties that are indeterminate in the pure state can somehow be regarded as determinate, because certain further measurements that would distinguish the pure state from the mixture are in practice impossible to perform. This can hardly be regarded as satisfactory for a fundamental theory of mechanics.

Quantum mechanics, interpretation of

Quantum mechanics developed in the early part of the twentieth century in response to the discovery that energy is quantized, that is, comes in discrete units. At the microscopic level this leads to odd phenomena: light displays particle-like characteristics and particles such as electrons produce wave-like interference patterns. At the level of ordinary objects such effects are usually not evident, but this generalization is subject to striking exceptions and puzzling ambiguities.

The fundamental quantum mechanical puzzle is 'superposition of states'. Quantum states can be added together in a manner that recalls the superposition of waves, but the effects of quantum superposition show up only probabilistically in the statistics of many measurements. The details suggest that the world is indefinite in odd ways; for example, that things may not always have well-defined positions or momenta or energies. However, if we accept this conclusion, we have difficulty making sense of such straightforward facts as that measurements have definite results.

Interpretations of quantum mechanics are, in one way or another, attempts to understand the superposition of quantum states. The range of interpretations stretches from the metaphysically daring to the seemingly innocuous. But, so far, no single interpretation has commanded anything like universal agreement.

1 Superposition of states

The *two-slit experiment* provides a vivid introduction to the concept of quantum superposition. Imagine a barrier with two slits, placed in front of a light source. On the other side of the barrier is a photographic plate. The intensity of the light can be made so low that photons (light quanta) hit the plate like particles, one at a time in definite though unpredictable locations. If we close the right slit, a narrow band of 'hits' will accumulate in front of the left slit. A similar result occurs if we close the left slit and keep the right one open. Now suppose both slits are left open. If photons were ordinary particles, we would predict two narrow bands of hits. What actually happens is *very* different: we get an array of bands, forming an interference pattern. If light were simply waves, this would not be mysterious: waves interfere. But individual photons are not waves. This leaves us wondering how the effect occurs and whether the individual photons even follow well-defined paths.

What does quantum theory say? Each of the one-slit experiments is associated with a particular *quantum state*. When we leave both slits open, the state becomes an odd amalgam - a *superposition* - of these. From the superposition we can derive a probability distribution for individual 'hits', a distribution that embodies the interference pattern. To say more than this, however, is to interpret quantum theory rather than simply to apply it.

Another example will make the notion of superposition more precise. Electrons have a directional property called *spin*. If we pick a direction and measure spin, we will always get one of two results: $+1$ or -1 ('up' or 'down'). Suppose we prepare a batch of electrons so that each would display spin up in measurement of spin in some specific direction x. It is usual to represent quantum states by abstract vectors in an abstract mathematical space called *Hilbert space* (see Quantum logic §2): in this instance, we will denote the quantum state of the electrons by the vector $|\,\mathrm{x}+\rangle$. Suppose now that instead of measuring x-spin we measure spin in a direction z at right-angles to x. We can use the rules of quantum theory to write $|\,\mathrm{x}+\rangle$ as a vector sum - a superposition - of z-spin states:

$$|\,\mathrm{x}+\rangle = \tfrac{1}{\sqrt{2}}\,|\,\mathrm{z}+\rangle + \tfrac{1}{\sqrt{2}}\,|\,\mathrm{z}-\rangle.$$

The numerical coefficients are used to calculate the probabilities of observing z-spin up or down in any given measurement. We get the probabilities by squaring these coefficients, in this case yielding a probability of 1/2 for each possible outcome.

Superpositions are not the same as mixtures. Suppose we prepare a batch of electrons of which half are in state $|\,\mathrm{z}+\rangle$ and half are in state $|\,\mathrm{z}-\rangle$. This is not a case of superposition. No matter what direction we choose for our spin measurement, the probabilities of spin up and spin down will be 1/2. This is very different to what we see in a superposition, for example, the state $|\,\mathrm{x}+\rangle$ discussed above. In this case, the probabilities depend on what direction we choose: for any direction in the x-z plane, the closer the direction to x the higher the probability of spin up will be, until the probability reaches certainty at x.

2 Superposition and the eigenvalue-eigenstate link

The example of spin illustrates some characteristic features of quantum mechanics. Quantum states are represented by vectors of length one in Hilbert space (an abstract mathematical shape). If we want to measure some quantity R (x-spin and z-spin being two examples of such quantities) on a system in state $\mid s\rangle$, our predictions typically involve probabilities. To find these, we write $\mid s\rangle$ as an appropriate sum of perpendicular vectors

$$\mid s\rangle = c_1 \mid r_1\rangle + c_2 \mid r_2\rangle + \ldots$$

For each possible measured value r_i of R, there is one vector $\mid r_i\rangle$. The measurable values r_i are called the *eigenvalues* of R, and the corresponding vectors r_i are the *eigenvectors* or *eigenstates* of R. If $\mid s\rangle$ happens to be one of the $\mid r_i\rangle$ - if c_i equals one and all the other c_i are zero - we predict the outcome r_i (the measurement of x-spin in the first system is an example of this: we predict that x-spin will be up, since $\mid s\rangle =\mid x\rangle$). If $\mid s\rangle$ is a superposition of the states $\mid r_i\rangle$, the probability of observing r_i in any given measurement is $\mid c_i \mid^2$. (As we saw when we measured z-spin in the first system for which $\mid s\rangle = (1/\sqrt{2}) \mid z+\rangle + (1/\sqrt{2}) \mid z-\rangle$). This rule is often referred to as the Born rule, after the physicist Max Born.

The conventional wisdom is that when $\mid s\rangle$ is a superposition of eigenstates of R, R has no definite value: so, for example, the electrons prepared with up x-spin have no definite z-spin. This principle is often called the *eigenvalue-eigenstate link*. Among other things, it would imply that the photons in the two-slit experiment do not go through either hole. To the uninitiated the principle might seem gratuitous, and in fact there is a classic argument that seems to undermine it. The modern formulation goes like this: we can produce a pair of electrons in a state called the *singlet state*:

$$\mid s\rangle = \tfrac{1}{\sqrt{2}} (\mid x_1+\rangle \otimes \mid x_2-\rangle - \mid x_1-\rangle \otimes \mid x_2+\rangle) \, .$$

Here $\mid x_1+\rangle \otimes \mid x_2-\rangle$ is a state in which electron #1 has x-spin up and electron #2 has x-spin down. $\mid x_1-\rangle \otimes \mid x_2+\rangle$ is read similarly. What this means is that, if we measure x-spin on electron #1, then an x-spin measurement on electron #2 *must* yield the opposite result no matter how well-separated #1 and #2 are. Furthermore, this holds for *all* directions: in the singlet state, parallel spin measurements *always* have opposite results. Therefore, we can predict the spin of particle #2 *in any direction we choose* by measuring particle #1. We cannot measure spin on electron #1 in two directions at once, and after the first measurement the correlation is broken: consequently, we cannot continue to accumulate information about electron #2 by repeated measurement on electron #1. But the correlation will hold for the first measurement of electron #1 that we make. Now, our measurement on electron #1 presumably does not *create* the spin of electron #2. Therefore, it apparently must have been there all along. The tempting conclusion is that electron #2 (and, by symmetry, electron #1) has a definite spin in each direction, even though *no* quantum state could tell us all those spins. If so, the eigenvalue-eigenstate link cannot hold.

This argument has its origins in the reasoning of Einstein, Podolsky and Rosen (1935), though it is not the version Einstein preferred (see Einstein, A. §5). Unfortunately, it is seriously flawed. Parallel spin measurements yield perfect anti-correlation. If the measurements are not parallel, the strength of the correlation varies with the angle. Suppose we assume that all spins are definite and that measurements on one electron do not affect the other. Can all the quantum predictions be captured consistently with the ordinary rules of probability? John Bell (1987) proved, roughly, that they cannot, and subsequent experiments have supported quantum theory's predictions. There are some loopholes here, but most physicists and philosophers agree that these results spell trouble for any wholesale rejection of the eigenvalue-eigenstate link (see Bell's theorem).

Unfortunately, retaining the eigenvalue-eigenstate link seems at least as bad. For one thing, we seem to accept that our measurement of electron #1 *does* create the spin of electron #2. Worse still, if the electrons are well separated their instantaneous 'communication' would seem to reguire faster-than-light signals, something which special relativity is usually held to forbid. There are more problems. Suppose we have an electron in the state $\mid x+\rangle$ and we decide to measure its z-spin. We would like the result to be a state in which the pointer indicates spin up or else a state in which the pointer indicates spin down. But Schrödinger's equation, the fundamental dynamical law of quantum mechanics, says that at the end of the measurement, we will get a superposition of such states, precisely because the state $\mid x+\rangle$ is not an eigenstate of the quantity (z-spin) which we are measuring. If we accept the

eigenvalue-eigenstate link, this implies, absurdly, that the measurement will fail to have a result in the oddest way possible: the pointer will not point anywhere at all (see Quantum measurement problem)!

3 Interpretations of quantum theory

Clearly quantum mechanics is puzzling. Interpretations of the theory usually focus on one or more specific puzzles, the measurement problem being the most notable. In what follows, we will look at a handful of interpretations and principles.

The most venerable is the Copenhagen interpretation, due to Niels Bohr (1935). Bohr maintains that physical concepts can only be applied in experimental contexts. This is not mere instrumentalism. Consider position and momentum. Both concepts are essential to quantum theory, but the experimental arrangements for measuring them are physically incompatible. Furthermore, the Heisenberg uncertainty relations guarantee that the more the state says about one, the less it says about the other. Bohr concludes that these concepts are *complementary*, and that each can be sensibly applied only within the appropriate experimental context.

On this view, the measurement problem is misconceived. It is a given that experiments have results. The function of quantum theory is not to tell a tale about how this comes to be, but to give an account of how the various possible experimental situations are related to one another.

A review of the literature reveals that the interpretation of the Copenhagen interpretation is no straightforward matter. Bohr may have been profound; few would claim he was clear. However, the stress on the need to ground physical concepts in experimental arrangements shows up in a different guise in a controversial principle called the projection postulate, first made explicit by von Neumann (1932). Schrödinger’s equation tells us that quantum states change smoothly and deterministically, but we have noted that this makes measurement puzzling. The projection postulate says that when we measure a quantity R, the state ’projects’ or ’collapses’ abruptly and unpredictably (but with probabitities determined by its coefficients, as above) on to one of R’s eigenstates, thereby leading to a definite measurement result.

One would like to know more. Does projection occur *only* during measurements? If so, what makes measurement special? Or does projection occur when a conscious observer enters the picture, as some interpreters claim? More recently, detailed physical theories of collapse have been offered. These amount to modifying quantum theory rather than merely interpreting it. The hope is that experiments will be able to settle the matter of whether collapses really occur.

Collapse theories deny that Schrödinger’s equation always holds. The most notorious approach that upholds Schrödinger’s equation is the many-worlds interpretation, which originated in Hugh Everett III’s relative state interpretation (1957) and was further developed by Bryce deWitt (1970). This account claims that when certain sorts of interactions occur, measurement being one of them, the universe divides into separate branches, one for each component of the superposition. This means that observers branch too, and that each observer on each branch sees one of the possible measurement results.

This approach strikes many people as metaphysically extravagant. If it fails, however, it will more likely be for technical reasons having to do with the rules governing branching (the so-called ’basis problem’) and the treatment of experimental probabilities.

Quantum logic is another scheme that seems to incorporate drastic measures. In fact, many different approaches, some quite harmless, fall under this rubric. Hilary Putnam made the most striking claims (1969). He maintained that quantum mechanics demands that we revise the laws of logic, notably the distributive law (’A and [B or C]’ is equivalent to ’[A and B] or [A and C]’). Putnam claimed that if we adopt quantum logic, all quantum paradoxes will vanish because it will be impossible to derive the apparent contradictions. He also maintained that, because statements like ’x-spin is up or down’ come out true on quantum logic, all quantities have values at all times, even though every attempt to list the values of all quantities would be inconsistent.

This is hard to understand, let alone believe, so much so that more or less no one believes it any more. However, a certain more general approach grew out of quantum logic, one that focuses on the mathematical structures underlying quantum mechanics. The hope is that by understanding the role of these structures in the theory, it will be possible to see quantum mechanics as providing explanations and not mere predictions (see Quantum logic;

Putnam, H. §4).

Finally, there are some important approaches that begin by rejecting the eigenvalue- eigenstate link, but do so in a carefully-limited way. One such is due to David Bohm (1952), but has its roots in deBroglie's 'pilot wave' interpretation. According to Bohm, particle positions are always definite. They evolve deterministically under the guidance of a 'quantum potential' operating in a space of $3n$ dimensions (*n* being the number of particles). This is the most well-worked out example of a hidden variable theory. Hidden variable theories have often been 'proved' impossible, but such proofs deal with theories that make *all* quantities definite or that deny faster-than-light causation. Bohm's theory accepts superluminal causation and takes position and functions thereof to be the *only* hidden variables. An oft-cited virtue of this approach is that it describes detailed processes underlying such cases as the two-slit experiment. The odd relationship to relativity is troublesome to many, but Bohm's theory continues to be an active area of research.

There are many other approaches to interpreting quantum mechanics and many issues that have not been raised here. For example, ensemble interpretations, which deny that the quantum state characterizes individual systems at all, are important. So-called 'modal' interpretations - a term introduced by van Fraassen - distinguish between what the state necessitates and what may actually be true in addition. Modal interpretations reject the eigenvalue-eigenstate link and have a certain kinship both with the many-worlds view (though without the extravagant metaphysics) and with hidden variables. The investigation of Bell's result led to much debate about whether there is any useful content to the idea that quantum mechanics incorporates some form of holism. And more recently, philosophers have turned their attention to foundational problems in quantum field theory (see Field theory, quantum).

The interpretation of quantum theory makes for an intriguing intersection between science and philosophy. The safest prediction is that the various controversies will not be settled soon.

(The decoherence programme attempts to give a *quantum mechanical* explanation of why the world normally appears classical. The account begins with the fact that virtually all the systems we encounter are *open systems*, that is, are in interaction with the environment. It goes on to argue rigorously that the result is a so-called ‘reduced density matrix’ (crudely, a restriction of the total state to a subsystem) that is a stable mixture of appropriate states. In the case of a measuring device, this would be a mixture of appropriate indicator states. Zurek is one of the main proponents of this approach and his article, though technical, is relatively accessible. The ‘Letters’ portion of the April 1993 issue of the same journal includes a number of reactions to Zurek’s essay, with replies by Zurek.)

Questions

Some theorists hold that a question is an interrogative sentence; others that a question is what is meant or expressed by an interrogative sentence. Most theorists hold that each question has two or more answers, and that the point of asking a question is to have the respondent reply with one of the answers. Most hold that each question has an assertive core or presupposition that is implied by each of the answers; if it is false, then no answer is true, so we say that the question commits the fallacy of many questions and we regard the negation of the presupposition as a corrective reply to the question (it corrects the question).

For example, consider the question 'Has Adam stopped sinning?' Its answers are 'Adam has stopped sinning' and 'Adam has not stopped sinning'. It presupposes 'Adam has sinned'; thus 'Adam has not sinned' is a corrective reply. The 'safe' way to ask this question is via the conditional 'If Adam has sinned, then has Adam stopped sinning?'

We can construct formal systems for asking whether *and* which *questions in an effective way. Other types of question (for example,* who *and* why*) are still problematic. It can be proved that some questions are reducible to others, some questions raise others, and some systems for the logic of questions can never be complete in certain ways.*

1 Concepts and theories

Questions have been discussed since Aristotle, although formal, systematic study did not begin until the 1950s. Theorists disagree on basic concepts, and there are at least three approaches to theorizing about questions. In one, the essence of a question is its set of answers, in another the essence is the questioner's intentions, and in another the essence is an objective intensional entity.

The 'reduction-to-answers' view holds that every question has direct answers, these direct answers are statements, and to know what counts as a direct answer to the question is to understand the question. A question presupposes any statement that is implied by every direct answer. A complete answer is a statement that implies a direct answer; a partial answer is a statement that is implied by a direct answer. The reduction-to-answers view is exemplified in most of the systems noted in §2 below.

The 'reduction-to-*intentions*' view holds that to know the questioner's intentions is to understand the question (see §4 below). The 'reduction-to-*intensions*' view holds that questions are intensional entities that are not relative to language and might or might not be expressible by sentences in a language (see §5 below and Intensional entities).

2 Effective systems

For many purposes (for example, conversation with strangers, courtroom procedure, automated information retrieval systems), it is desirable to have systems for question and answer that are effective in the following sense: for any expression of the given language, we can effectively tell whether it is an interrogative sentence and, if it is one, tell what question it expresses. In the reduction-to-answers view this implies that, given an interrogative sentence, we can effectively tell what counts as a direct answer to the question that is expressed.

Beginning with G. Stahl and T. Kubiński in the 1950s, logicians have constructed systems that provide for *whether* and *which* questions and that satisfy the effectiveness condition. The system of Belnap and Steel (1976) is exemplary. In it, *whether* and *which* questions are expressed by interrogatives of the form *?RS*. Here the subject part *S* indicates a set of statements, which are the alternatives presented by the question. (For *whether* questions *S* is a finite list of statements; for *which* questions *S* is a formula indicating all the statements that result when names are substituted for the queriables (the free variables) in the formula.) Given *S*, the request part *R* indicates how many of the true alternatives are to be put into each direct answer and indicates whether the answer is to claim that it contains all of the true alternatives and (in the case of *which* questions) claim that the various names given in the answer denote distinct entities. The system provides for *who*, *when*, *where*, *why*, *what* questions - if these are construed as asking which person, which time, which place, which reason, which thing. It allows the questioner to call for a complete list or just some examples or an answer of the form at-least-*m*-but-at-most-*n*.

3 Some problems

Systems such as those noted above are good models for some question-asking situations but not for others. First consider ‘What is in the box?’ and ‘Some of John’s things are in the box’. If the latter is a complete answer, as some theorists say, then this *what* question cannot be construed as a *which things* question, and the system must be altered or extended to provide for it. Similar examples exist for *who* and other so-called ‘wh- questions’.

Why questions pose special problems. Consider ‘Why did this apple fall?’. We may construe this as ‘What is a good explanation of why this apple fell?’, but we will not know what counts as an answer until we know what counts as a good explanation. S. Bromberger (1992) has proposed that some types of *why* question can be adequately answered by citing (1) a general rule, (2) an abnormic law - that is, a law that specifies exceptions to the rule, and (3) some exception mentioned by the law. For example: ‘An apple remains on the tree unless it becomes ripe or a wind blows or the tree dies, and in this case the wind blew.’ It is reasonable to require that the abnormic law be empirical and true, but then (because we cannot always recognize truth) we cannot always recognize the admissible direct answers.

Effective systems have some intrinsic limitations. Suppose that the interrogatives of a system can be effectively recognized and hence listed by some algorithm and that, for each interrogative, its direct answers can be recognized and hence listed. Then it can be shown by Cantor’s diagonal method that the system is incomplete in the sense that there is a set of sentences that might be the answers to some question but cannot be the answers for any interrogative in the given list (Harrah 1984).

4 Epistemic analysis of questions

L. Åqvist (1965) proposed that questions are requests concerning epistemic states, expressible by imperatives such as ‘Let it be the case that I know that *A* or I know that *B*’ or ‘Let it be the case that, for some *x*, I know that *Px*’. In this approach there may be a variety of imperative operators, and reference made to different knowers, so that, for example, a teacher can put questions to a class in the form ‘Bring it about that I know that you know…’ J. Hintikka (1983) has developed this approach further to elaborate its pragmatic dimension. Hintikka has extended his game-theoretic semantics to provide a semantics for epistemically construed questions and rules for conducting various types of rational question-and-answer dialogue (see Semantics, game-theoretic).

In this approach every question has a presupposition (in the first example above: ‘*A* or *B*’), a desideratum (‘I know that *A* or I know that *B*’) and direct answers (*A*, *B*). If an answer meets certain conditions of relevance and conclusiveness, guaranteeing that the desideratum is satisfied, then it is a conclusive answer. The conditions vary with the type of question. In the case of a *which* question, quantified variables should range over entities with which the questioner is acquainted, and the answer should specify a noun phrase only if the questioner knows what that phrase denotes. There is no guarantee that the respondent can effectively tell from the imperative sentence what the range of the variables is supposed to be, or what noun phrases will suffice, so, in this approach, the concept of conclusive answer in general is not effective.

5 Intensional analysis of questions

P. Tichý (1978) proposed that a question is a function defined on possible worlds. Propositions, individual concepts and properties are such functions, and they are the common types of question. For any given world the value of such a function is a truth-value, an individual or a set of individuals, respectively. In general the right answer to a question is the value of the function in the actual world.

This idea can be developed on its own; it can also be combined fruitfully with the ideas of Richard Montague. In Montague’s analysis of declaratives, meanings are higher-order intensional entities. These are assigned to linguistic expressions according to Frege’s principle that the meaning of a syntactical compound is the corresponding semantic compound of the meanings of the parts of the syntactical compound. Some linguists and logicians have developed analyses of this sort that treat both declaratives and interrogatives. In most, an interrogative expresses a question and denotes its true direct answers (see Frege, G.).

6 Erotetic logic

In a general sense erotetic logic is the logic of utterance and reply (Harrah 1984). In the strict sense it is the logic

of question and answer.

For most systems, especially those noted in §2 above, an important concept is that of containment. One question contains (or covers, or obviates) another if and only if every direct answer to the first implies some direct answer to the second, and two questions are equivalent if and only if each contains the other.

For analysis of the raising of questions, the implying of questions and arguing to questions, Wiśniewski (1995) has defined some useful concepts. For example: A set of declarative sentences evokes a question if and only if the set implies that the question has a true direct answer but does not imply the truth of any particular direct answer. Also, one question implies another if and only if each direct answer to the first implies that some direct answer to the second is true and for each direct answer to the second there is a proper subset (that is, a small selection) of direct answers to the first such that the given direct answer to the second implies that a true direct answer to the first is contained in that subset (so each true answer to the second helps us find a true answer to the first).

Another of Wiśniewski's concepts is that one question is reducible to a set of other questions (call it the reducing set) if and only if each direct answer to the given question implies that all the questions in the reducing set have true direct answers; and each collection of sentences that contains exactly one direct answer to each question in the reducing set implies some direct answer to the given question; and no question in the reducing set has more direct answers than the given question does. One result is that, if a question is 'safe' (that is, in every interpretation of the language the question has a true direct answer), then the question is reducible to some set of simple yes-no questions.

Quine, Willard Van Orman (1908-)

Quine is the foremost representative of naturalism in the second half of the twentieth century. His naturalism consists of an insistence upon a close connection or alliance between philosophical views and those of the natural sciences. Philosophy so construed is an activity within nature wherein nature examines itself. This contrasts with views which distinguish philosophy from science and place philosophy in a special transcendent position for gaining special knowledge. The methods of science are empirical; so Quine, who operates within a scientific perspective, is an empiricist, but with a difference. Traditional empiricism, as in Locke, Berkeley, Hume and some twentieth-century forms, takes impressions, ideas or sense-data as the basic units of thought. Quine's empiricism, by contrast, takes account of the theoretical as well as the observational facets of science. The unit of empirical significance is not simple impressions (ideas) or even isolated individual observation sentences, but systems of beliefs. The broad theoretical constraints for choice between theories, such as explanatory power, parsimony, precision and so on, are foremost in this empiricism. He is a fallibilist, since he holds that each individual belief in a system is in principle revisable. Quine proposes a new conception of observation sentences, a naturalized account of our knowledge of the external world, including a rejection of a priori knowledge, and he extends the same empiricist and fallibilist account to our knowledge of logic and mathematics.

Quine confines logic to first-order logic and clearly demarcates it from set theory and mathematics. These are all empirical subjects when empiricism is understood in its Quinian form. They are internal to our system of beliefs that make up the natural sciences. The language of first-order logic serves as a canonical notation in which to express our ontological commitments. The slogan 'To be is to be the value of a variable' ([1953] 1961: 15) encapsulates this project. Deciding which ontology to accept is also carried out within the naturalistic constraints of empirical science - our ontological commitments should be to those objects to which the best scientific theories commit us. On this basis Quine's own commitments are to physical objects and sets. Quine is a physicalist and a Platonist, since the best sciences require physical objects and the mathematics involved in the sciences requires abstract objects, namely, sets.

The theory of reference (which includes notions such as reference, truth and logical truth) is sharply demarcated from the theory of meaning (which includes notions such as meaning, synonymy, the analytic-synthetic distinction and necessity). Quine is the leading critic of notions from the theory of meaning, arguing that attempts to make the distinction between merely linguistic (analytic) truths and more substantive (synthetic) truths has failed. They do not meet the standards of precision which scientific and philosophical theories adhere to and which are adhered to in the theory of reference. He explores the limits of an empirical theory of language and offers a thesis of the indeterminacy of translation as further criticism of the theory of meaning.

1 Life

Willard Van Orman Quine was born on 25 June 1908. He was an undergraduate at Oberlin College and a graduate student at Harvard, where he studied with A.N. Whitehead, C.I. Lewis and Sheffer. In his dissertation 'The Logic of Sequences: A Generalization of *Principia Mathematica*' there already appears a prominent theme of Quine's philosophy - a concern with matters of ontology (Quine 1934).

In 1931, Quine had what he has described as his 'most dazzling exposure to greatness', when Bertrand Russell came to lecture at Harvard. Russell is one of the most influential figures on Quine's thought. Both share a preoccupation with questions concerning what there is. For example, Quine adopted and improved upon Russell's view of how we express ontological claims. More significantly, as the dissertation already reveals, Russell's influence was that of a rival whose theories spur Quine on to the creation of more acceptable alternatives. Wherever possible, Quine tries to get on with the fewest and most precise assumptions which will suffice to do the job at hand. Whereas *Principia Mathematica* is constructed on the basis of an ontology that comprises propositional functions, which are properties of a sort, Quine's revision tries to accomplish the same goals with concrete physical objects and sets or classes. In addition, some of Quine's most famous systems of logic and set theory are designed to achieve the same effects as *Principia Mathematica*, while avoiding Russell's theory of types (see Theory of types).

A travelling fellowship to Europe in 1932 exposed Quine to the latest developments in logic and in philosophy. In

Vienna he attended meetings of the Vienna Circle, and described the following weeks spent in Prague and Warsaw as 'the intellectually most rewarding months I have known' (see Vienna Circle). In Prague, Quine met Rudolf Carnap, one of the most careful expositors of prominent themes of analytic philosophy and especially those of the logical empiricists, such as the verifiability criterion for the empirical meaningfulness of sentences, the linguistic (analytic) character of a priori knowledge, as in mathematics and logic, and the triviality or meaninglessness of ontology as a species of metaphysics. Quine subjected each of these themes to severe criticism, resulting in some of the most important philosophical debates of the century. In Warsaw, he attended the lectures of Lesniewski, Łukasiewicz and Tarski and in the next few years was to adopt Tarski's and Gödel's 'classic' formulation of logic in formulating his most famous works. Quine was quite sympathetic to the extensionalist and the nominalist side of the Warsaw school.

At Harvard in the period prior to the Second World War, Quine worked out some of his most distinctive positions: his conception of ontological commitment (best known from his 1948 essay 'On What There Is'); his two most distinctive systems of logic and set theory 'New Foundations for Mathematical Logic' (1937) and *Mathematical Logic* (1940); and his criticisms of the position that a priori knowledge as it purportedly exists in logic and mathematics is merely linguistic. These criticisms began to appear in 1934, when Quine lectured on Carnap's work. Some of this material can be found in 'Truth by Convention' (1936) and his most famous paper, 'Two Dogmas of Empiricism' (1951).

Quine served as a naval officer in the Second World War, and after continued his work on the above topics (see *From a Logical Point of View* (1953)). Much of his most original work since then has been the formulation of a new holistic variety of empiricism and the exploration of its consequences: 'The point of holism, stressed by Pierre Duhem…, is that the observable consequence by which we test a scientific hypothesis is ordinarily not a consequence of the hypothesis taken by itself; it is a consequence only of a whole cluster of sentences… ' (1987: 141). Beginning with 'Two Dogmas', and eventually in *Word and Object* (1960), Quine employed this new holistic empiricism to criticize the concepts of meaning, synonymy and analyticity. In *Word and Object* he presented a thesis of the indeterminacy of translation as a further criticism of these notions. Later, in *Ontological Relativity* (1969), *The Roots of Reference* (1974), *Pursuit of Truth* (1992) and *From Stimulus to Science* (1995) he took a similar critical stance on concepts from the theory of reference. In essays dating from this period Quine's naturalism also comes to the fore. Though the theme of the continuity of philosophy and science is found in earlier works, he explores it more explicitly in 'Epistemology Naturalized' (1969), *Theories and Things* (1981), *Pursuit of Truth* and *From Stimulus to Science*.

2 Epistemology naturalized - nature know thyself

The problem of our knowledge of the external world is traditionally stated as one of how a self with private mental states can come to have knowledge of the external world. Quine's restatement is strikingly more naturalistic:

> I am a physical object sitting in a physical world. Some of the forces of this physical world impinge on my surface. Light rays strike my retinas; molecules bombard my eardrums and fingertips. I strike back, emanating concentric air waves. These waves take the form of a torrent of discourse about tables, people, molecules, light rays, retinas, air waves, prime numbers, infinite classes, joy and sorrow, good and evil.
>
> (Quine 1966: 215)

In its traditional statement the problem lies in how, starting with 'experience' in the form of immediately given impressions or sense-data, we justify our claims to know objects such as tables, chairs or molecules. This vantage point was that of a first philosophy, intended as providing a foundation of certainty for the sciences by standing outside of them and legitimizing their accomplishments. Quine rejects this formulation. His naturalized epistemology rephrases the problem as one of how we learn to talk about or refer to objects (ordinary as well as scientific). What are the conditions that lead to reference? How is scientific discourse possible?

The traditional accounts of the linkage between 'experience' and our knowledge vary from mentalistic conceptions, like that of Hume, in which all our ideas are copies of sense impressions, to more neutral linguistic formulations, in which cognitive claims are to be translated into observation sentences. On Quine's holistic account, one cannot deal with the empirical content of sentences, much less of terms - the linguistic correlates of ideas - one by one, either via definition, translation or some other sort of linkage. To study the relation of

knowledge and science to observation sentences is to trace the psychological and linguistic development of the knower, that is, the potential user of scientific language. Observation sentences serve as both the starting point in human language learning as well as the empirical grounds for science. The problem of knowledge now is how, starting with observation sentences, we can proceed to talk of tables, chairs, molecules, neutrinos, sets and numbers. One of the reasons for doing epistemology by studying the roots of reference is simply the failure of the traditional empiricists' programme mentioned above. Another is that it enables one to dispense with mentalistic notions such as 'experience' or 'observation'. One relies instead on two components which are already part of a naturalist's ontology: the physical happening at the nerve endings, the neural input or stimulus; and the linguistic entity, the observation sentence. These two serve as naturalistic surrogates for 'experience' and 'observation'. On Quine's empiricist and behaviourist account, observation sentences are those that can be learned independently of other language acquisition. They are the sentences that can be learned purely by ostension and as such are causally most proximate to the stimulus. This account is not vulnerable to attacks on the notion of observation as dependent on the theories one holds, since observation sentences are precisely those which are learnable without any background information. Another point of difference with empiricists concerns the alleged certainty or incorrigibility of observation. Though Quine's observation sentences are assented to with a minimum of background information and are thus included among those sentences less likely to be revised, they are not in principle immune from revision.

Unlike traditional epistemology, then, Quine's epistemology is naturalistic: we cannot stand apart from our place as part of nature and make philosophical judgments (see Naturalized epistemology). This is part of the theme that philosophy is continuous with science, science being the part of nature most suitable for knowing itself.

> The naturalistic philosopher begins his reasoning within the inherited world theory as a going concern. He tentatively believes all of it, but believes also that some unidentified portions are wrong. He tries to improve, clarify and understand the system from within.

3 Dethroning the a priori

A purported stumbling block for empiricism is a priori knowledge in logic and mathematics and in such purportedly conceptual truths as 'All bachelors are unmarried' and 'Nothing is larger than itself'. Such subject matter appears to defy justification in terms of observation. J.S. Mill's empiricist programme foundered on this point, and the various forms of rationalism are unacceptable to an empiricist. A proposed solution, the dominant one favoured by analytic philosophers, involved the analytic-synthetic distinction: all a priori knowledge was said to be analytic, in the sense that the truth of sentences claimed to be known independent of experience was reducible to matters of language, for example, linguistic convention, definitions, and truth in virtue of the meaning of the expressions involved.

Quine's critique is that of an empiricist reforming empiricism, supplanting reductionist-atomistic empiricism with Duhemian holism. Experimental testing is a juncture where observation ('experience') enters as a factor in deciding whether to accept or reject a claim. An oversimplified model of how observation counts in testing is that given a hypothesis and a statement of initial conditions, we deduce by logic and/or mathematics some observation sentence as an observable consequence. If the expected observation occurs, we take this as evidence for the hypothesis. If it does not, we take this as evidence that the hypothesis is false. Such a model makes use of the dogma of reductionism by assuming that individual sense experiences-observation sentences function unequivocally for or against isolated sentences-hypotheses. Pierre Duhem showed that this model is flawed and Quine extends Duhem's point into a holistic one that embodies a critique of reductionism and the a priori.

Duhem had pointed out that where the observation fails to occur, one has leeway in dealing with the situation. All serious testing involves background assumptions, implicit in the hypothesis or in the statement of the initial conditions. A test situation underdetermines which factor should be revised and there is no way of knowing in advance where the revision should be made. Quine's insight was to take cognizance of all the assumptions that can be questioned in a test situation. The underdetermination of theory by observation does not stop with revising background assumptions relative to the hypothesis and the initial conditions. Both the purportedly disconfirming observation made and the principles involved in deriving the observable consequence can also be revised. In test

situations whole systems of beliefs go into the hopper and we have leeway as to how we make the consistency-preserving revisions. We can edit the observation. We can even question the logic and or mathematics used in deriving the observable conclusion. No sentence is in principle immune from being revised. In this spirit, all knowledge is empirical; there is no a priori knowledge. The quest for certainty is replaced by fallibilism, the associated foundationalist programmes are abandoned, as is the verifiability theory of the logical empiricists. Instead, the broad constraints on what to do in a test situation are the natural scientist's criteria for preferring one hypothesis, theory or system of beliefs over another. These criteria include explanatory power, simplicity or parsimony, conservatism, modesty and precision (1970: 54). Conservatism cautions, other things being equal, that we should accept that hypothesis-theory which clashes least with our other beliefs. This 'maxim of minimal mutilation' comes into play in explaining why logic, while in principle revisable (for example, some suggest adopting a three-valued logic), is the least likely item to be revised. Doing so would have far-reaching consequences for our other beliefs. Modesty says that all other things being equal we should hypothesize as little as is necessary for the job at hand. Precision mandates standards on introducing and explaining philosophical or scientific concepts. It requires that philosophical explications be couched in acceptable terms, the extensional or empirical notions of logic, set theory and the sciences. For example, abstract objects should not be posited without a precise account of what they are, that is to say, 'no entity without identity' (see A Priori §1; Analyticity §§1-3; Fallibilism).

4 Logic as first-order logic

Quine distinguishes the theory of reference from the theory of meaning. He is sceptical of notions associated with the theory of meaning, such as those of meaning, intension, synonymy, analyticity and necessity. By contrast, he relies on and makes contributions to the theory of reference, for example, to the understanding of logical truth, truth, reference and ontological commitment.

For Quine, the notion of logical truth falls squarely in the theory of reference. His most characteristic definition of logical truth is that a sentence is a logical truth if it is true and if it remains true when one uniformly replaces its nonlogical parts. The logical parts are the logical constants, signs for negation, disjunction, quantification and identity. 'Brutus killed Caesar or it is not the case that Brutus killed Caesar' is such a logical truth. In Quine's terminology the logical constants 'or' and 'it is not the case that' occur essentially, while the nonlogical part 'Brutus killed Caesar' can be uniformly varied and the resulting sentence will still be true. In other words a logical truth cannot be changed into a falsehood by varying the nonlogical expressions, whereas an ordinary truth can be.

The same concept of logical truth is found in Bolzano and Ajdukiewicz. One of its virtues lies in its being parsimonious, that is, in what it does not say. Logical truth and related notions are often explained in modal terms. That is, logical truths are said to be distinguished by being 'necessary' or 'true in all possible worlds', and a valid argument is defined as one in which, if the premises are true, the conclusion 'must be true'. These accounts make logic presuppose modal notions. Quine's definition leaves logic autonomous in this respect. Indeed Quine is a critic of modal logic, challenging various attempts to explain the notion of necessity. Logical truth, as defined by Quine, is a precisely explained species of truth, fitting squarely inside the theory of reference. Quine relies on the concept of truth, which he construes along the lines of Tarski's theory (see Tarski's definition of truth).

If logical truths are those in which only logical constants occur essentially, then the scope of logic is in part determined by what we take to be a logical constant. Quine lists as the logical constants the truth-functional connectives 'not', 'and', 'or', 'if… then', 'if and only if'; the quantifiers 'all' and 'some'; and the identity predicate '$a = b$'. The language of logic so construed is that of sentences formed out of truth-functional connectives, quantifiers, identity, schematic predicate letters and individual variables. Quantificational logic of this sort is also known as first-order logic. For Quine, logic *is* first-order logic with identity. Ruled out as logic on this construal are modal logic, because 'necessity' is not taken as a logical constant. Also excluded is higher-order logic, which has quantifiers for predicate positions (it is 'set theory in sheep's clothing' (1986: 66)). On other grounds other proposals such as intuitionist logic are also ineligible. Set theory, and with it mathematics, are not logic (see Logical constants §§1-2).

Quine falls in the camp of the Logicist programme in holding that mathematics is reducible to set theory. Set theory is the theory of the 'is a member of' predicate and is stated in the language of first-order logic. Given the theory of membership and logic as first-order logic plus identity, Quine introduces mathematical notions as

definitional abbreviations: for example, a number is defined as a special set, addition as a special function on these sets and so on. He argues that logic does not include set theory because membership should not be considered a logical constant for the following reasons: (1) There is a general consensus about elementary logic, which, given paradoxes such as Russell's, is lacking in the case of set theory. Alternative set theories have the status of so many tentative hypotheses. This lends credence to Quine's view that mathematics based on set theory is not very different from other sciences. (2) The incompleteness of set theory contrasts sharply with the completeness of elementary logic. (3) The ontology of set theory is not as topic neutral as that of logic. The second item in the membership relation is restricted to sets. Logic is the most general of subjects, since the variables of logic are not restricted to any one category of objects (see Logicism §1).

5 Canonical notation and ontological commitment

Ever since Frege and Russell, existential quantification has been the prevalent way in which existence assertions have been understood. The idea is that existence sentences in natural language can be paraphrased in the language of logic and 'existence' explicated by the existential quantifier of predicate logic. 'Existence is what existential quantification expresses' (1969: 97). The functions that the predicate 'exists' performs in English can be accomplished by the '$\exists x$' quantifier. Quine's version of this theme is incorporated into his account of ontological commitment. The language of first-order predicate logic in which our ontological commitments are made is his 'canonical notation'.

> Taking the canonical notation thus austerely… we have just these basic constructions: predication, quantification… and the truth functions… What thus confronts us as a scheme for systems of the world is that structure so well understood by present-day logicians, the logic of quantification or calculus of predicates.
>
> Not that the idioms thus renounced are supposed to be unneeded in the market place or in the laboratory… The doctrine is only that such a canonical idiom can be abstracted and then adhered to in the statement of one's scientific theory. The doctrine is that all traits or reality worthy of the name can be set down in an idiom of this austere form if in any idiom.
>
> It is in spirit a philosophical doctrine of categories, … philosophical in its breadth however continuous with science in its motivation.
>
> (Quine 1960b: 228-9)

A key reason for regarding this language as canonical is that in it one's use of the existential quantifier is explicit. To discover the existence assumptions or ontological commitments of a theory, we first state it in the language of truth-functional connectives and quantification, and then look at the existential quantifications we have made. The logic of '$\exists x$' is the logic of existence, and a notation that makes '$\exists x$' explicit accordingly makes our existence assumptions or ontological commitments explicit.

One of Quine's most famous remarks, 'to be is to be the value of a variable' ([1953] 1961: 15), sums up this criterion of ontological commitment. The slogan also incorporates one of Quine's elaborations on Russell's theory of definite descriptions. Russell held that in most sentences ordinary names are disguised definite descriptions, which on his theory are analysed as existential generalizations. Thus 'Socrates is human' becomes 'The one husband of Xanthippe is human' which in turn becomes the existential generalization 'There is one and only one husband of Xanthippe and he is human'. Quine's elaboration dispenses with names entirely. Wherever a name occurs in the original sentence, we can get by in the canonical notation with variables, predicates and the logical constants. If we do not have a definite description on hand to put in place of the name, we can form a predicate, such as 'Socratizes', then encapsulate the coined predicate in a definite description and define away the descriptions via Russell's theory. So names disappear and are not part of the canonical notation. Dispensing with names not only has the virtue of a more parsimonious notation: it also specifies that variables are the vehicles of reference and as such the grounds of ontological commitment. Being the value of a variable is what 'being' is all about (see Logical form; Ontological commitment).

6 Competing ontologies

Some important philosophical differences concern competing ontologies. Physicalists, for instance, have as their basic objects physical objects, while phenomenalists have sense-data. A twentieth-century version of the problem

of universals involves a dispute over the relative merits of (1) a nominalistic ontology according to which only concrete individuals exist; and (2) realist ontologies, such as those of Platonists, which involve the existence of abstract objects. The issue of nominalism versus Platonism arises for Quine in connection with the mathematics required for science and the question whether it requires hypothesizing abstract objects such as sets. Another area of ontological controversy is whether Platonist assumptions should include only extensional objects such as sets or intensional ones such as properties or propositions (see Abstract objects §3; Nominalism §4.

While we look to the existential generalizations of a theory stated in canonical notation to see what its ontological commitments are, this does not answer the question of which ontological commitments we should have. As a naturalist and scientific realist, Quine regards this as a matter of epistemology. It is the question of which theory we ought to accept. Deciding on a theory (scientific or philosophical) and its attendant ontology is once again done within a scientific perspective. Appeal is made to the same theoretical concerns mentioned earlier, that is, explanatory power, parsimony, conservatism, precision and so on. Quine's own ontological commitments are the result of just such considerations. He is a physicalist, no longer taking seriously the phenomenalist programme; partly on grounds connected with the dogma of reductionism and partly on the grounds that sense-data are not needed in a naturalized epistemology (the functions performed by sense-data are accomplished by nerve hits and observation sentences which are already part of our physicalist ontology). But he is a Platonist (a reluctant one) because of the mathematics that is required by our best scientific theories. In canonical notation, this mathematics requires quantifying over at least as many extensional abstract objects, namely sets, as there are real numbers. In an early essay co-authored with Nelson Goodman, 'Steps Towards A Constructive Nominalism' (1947), the possibilities of taking a nominalist stance were surveyed. But unlike Goodman, Quine reluctantly concluded that the nominalist programme failed. He has considered later attempts at nominalism such as by an appeal to substitutional quantification. The success of these attempts depends on whether impredicative notions are required by the mathematics embedded in the natural sciences. Others (Field 1980) try to make the case for nominalism by abiding by some and abandoning other of Quine's constraints.

However, Quine has consistently argued against theories which require abstract objects of an intensional sort. An intensional notion might provisionally be characterized as one requiring for its explanation notions which do not conform to certain basic assumptions of first-order logic and standard set theories. Intensional contexts are not truth-functional, or do not allow the substitutability of coextensive singular terms or predicates. Modal notions are a case in point. 'Necessarily P' is not a truth-functional operation; we cannot replace singular terms or predicates in P, or the whole sentence P, with coextensive expressions and be guaranteed that if the original sentence is true then the subsequent one will also be true. In non-intensional contexts, that is, extensional contexts, such replacements are truth-preserving. Intensional objects are those that require intensional notions to account for them, such as properties or propositions. Extensional objects are those that do not require intensional notions to account for them, such as sets or sentences. So sets are identical if they have the same members, for example, the set of humans is the same as the set of featherless bipeds. Properties, on the other hand, are identical only if they necessarily belong to the same objects. So the properties of being human and being a rational animal are identical, but differ from the property of being a featherless biped.

Given Quine's views on the precision of notions from first-order logic and set theory, it is not surprising that he is critical of intensional notions which are not based on standard assumptions of first-order logic and set theory. His arguments against hypothesizing intensional objects are numerous and can be sketchily listed as cases where their explanatory power is questioned, where parsimony is invoked and where precise accounts of the identity conditions of such items is lacking ('no entity without identity'). Sometimes he argues that extensional ersatz constructions can achieve the same purpose for which the intensional objects were introduced: for instance, eternal sentences rather than propositions, sets rather than properties, ordered pairs rather than relations (construed intensionally), non-modal notions rather than modal ones, and so on (see Intensional entities §1).

7 Indeterminacy of reference and global structuralism

Quine's views on ontology undergo refinements in his later writings. Most important is the recognition that empiricism does not uniquely determine which objects are required as the values of our variables. There is an indeterminacy of reference which is in keeping with empiricist strictures on deciding which ontology to accept.

The thesis of ontological relativity, also known as the inscrutability or indeterminacy of reference, is in accord

with Quine's naturalistic empiricism. It has been generalized into a view which he refers to as global structuralism. Since it is only at the observation sentences construed holophrastically as indissoluble wholes that the system is externally constrained, there are different but equally plausible ways of meeting these observational constraints and these can involve diverse ontologies, such as an ontology of rabbits or of rabbit parts. It is the structural part of the system that must be saved in order to meet the observational constraints. But this can be accomplished with quite different objects being the values of the variables. Quine endorses this global structuralist perspective by generalizing from his own cases and by noting a less global structuralist argument from the philosophy of mathematics. Quite different objects can be taken as the values of the variables for arithmetic, for example, numbers can be taken as Frege-Russell sets or as von Neumann sets without changing the truths of arithmetic. For Quine the question of whether we are really committed to rabbits as opposed to sums of rabbit parts, or to a given number as the set of all sets equinumerous to a given set (as on the Frege-Russell account) or to some different set (as on von Neumann's view) is without sense. It is without sense in that there is no natural-empirical way of raising this question. Global structuralism is a consequence of the denial of a first philosophy - a point of view in nature that transcends all natural points of view.

Quine's best-known cases which serve as evidence for his global structuralism are his rabbits case and his proxy functions, especially that of cosmic complements. Intertwined with his discussion in *Word and Object* of a linguist translating a native speaker's utterance of 'Gavagai', Quine points out that construing that expression as a referring expression leaves no empirical way of deciding whether it is used to refer to rabbits, rabbit parts, or rabbit stages and so on. As a later example he asks us to consider how sentences about concrete objects can be reinterpreted in terms of different ontologies assigned as values of the variables so that there is no empirical way of saying which is the correct one. Indeed the message of structuralism is that it is an error to speak as though there were a uniquely correct referent. The sentence 'This rabbit is furry' is true and is usually interpreted as being about individual rabbits and individual furry things. However, if we reinterpret the referring portions in terms of mereological cosmic complements the sentence remains true and there is no empirical way if we do this uniformly to say which is the correct ontology. Thus assign to 'This rabbit' the entire cosmos less this rabbit (imagine a complete jigsaw puzzle with a rabbit piece removed; the cosmic complement would be the puzzle without the rabbit piece). Assign to the predicate 'is furry' each of the cosmic complements of individual furry things. The sentence 'This rabbit is furry' is true under such an interpretation because the cosmos less this rabbit is a member of the set of cosmic complements of individual furry things (that is, that set includes the cosmic complement of that individual rabbit). One can extend this treatment of singular sentences to the remaining referential sentences.

8 The theory of meaning: its myths and dogmas

Quine's reaction in the 1930s to Carnap's work was a sceptical critique of the prevalent view among analytic philosophers that logic and mathematics are justified in some distinctively linguistic way, that is, that they are based on merely analytic-linguistic truths - truths by convention. The scepticism then and later questions proposed accounts of the distinction. Linguistic truth or truth by convention, as opposed to non-conventionally based empirical truths, appears in the end to be a purported distinction without a real difference. Of special importance is the failure to satisfy the requirement of precision in explaining the distinction. In 'Truth By Convention' (1936) and 'Carnap on Logical Truth' (1960a), Quine takes up different attempts to characterize such truths and finds that for the most part they are either too broad - not distinctive of logic or mathematics - or require non-linguistically based truth. There are as many of these characterizations as there are different senses of 'convention'. Quine considers truth by convention as based on the following: the arbitrary factor in axiomatization; formalization-disinterpretation; the arbitrary element in hypothesizing; and definition. But neither logic nor mathematics is distinguished by being axiomatized, or formalized-disinterpreted. The same can be done for other disciplines, such as physics and biology. The somewhat arbitrary choice of which sentences to take as axioms, so long as we can prove the right sentences, is also not distinctive of them. If truth by convention is taken as the somewhat arbitrary element in framing hypotheses, then this too is not distinctive of logic or mathematics. Nor are the formulas involved distinguished by being true by definition. Thus, if '$p \rightarrow p$' is defined in terms of '$-p \vee p$', then the truth of the defined formula depends on the truth of the defining formula, and that formula's truth is not a matter of definition or convention. For Quine, logic and mathematics can be precisely characterized in terms from the theory of reference. Logic is described in terms of truth, the logical constants and interchange of the extralogical elements; mathematics can be characterized in terms of set theory. But neither of these subjects is

distinct in having a different epistemological basis which results in their being in some interesting sense ‘analytic’ or mere ‘linguistic truths’.

The ‘Two Dogmas’ of Quine’s 1951 essay were the dogma of reduction (see §3 above) and the dogma of the analytic/synthetic distinction. In discussing the dogma of analyticity, Quine questions, as he did in ‘Truth by Convention’, whether the distinction can be well made. Here he rejects five ways of explaining analyticity. These involve appeals to: (1) meanings, (2) definition, (3) interchangeability, (4) semantic rules and (5) the verifiability theory of meaning.

(1) ‘Bachelors are unmarried men’ might be regarded as analytic, where that notion is explained as truth in virtue of the meanings of its words. One suggestion is that the meaning of ‘unmarried man’ is included in the meaning of ‘bachelor’. Another approach would hypothesize the existence of meanings to explain synonymy and then use synonymy in turn to show how the above sentence is a synonymous instance of a logical truth. The success of the above explanations requires assuming that there are such things as precisely characterizable meanings. Quine is sceptical of this assumption. He rejects three accounts of meanings: (a) referential theories - meanings as referents; (b) mentalism - meanings as ideas; and (c) intensionalism - meanings as intensional entities. Meaning (or sense), as Frege taught, must be distinguished from reference. The notion of meaning that is to explain synonymy and analyticity cannot simply be reference, because coreferential terms need not be synonymous and so will not distinguish analytic sentences from true non-analytic ones. Truth in virtue of meaning where meaning is simply reference is too broad as all truths would then be analytic. As to meanings as ideas, Quine brings to bear empiricist and behaviourist qualms. The account of meanings as abstract intensional entities is found in Frege, Carnap and Church. Quine maintains that such intensional objects are neither required as posits by our theories of language, nor are they precisely accounted for. The attempt to explain intensional notions is either circular or unhelpful. There is a circle of intensional notions, meaning, synonymy, analyticity, necessity, and we can define one in terms of another. Quine’s criticism is that if we do not break out of this intensional circle, then the account has failed to clarify the matter. For example, if the meaning of a predicate ‘is human’ is the property of being human, how would one go about identifying whether ‘being a rational animal’ or ‘being a featherless biped’ stood for the same property or had the same meaning? One answer is that the sentence ‘humans are rational animals’ is analytic, while the sentence ‘humans are featherless bipeds’ is not. But this relies on the notion of ‘analytic’ - which we haven’t yet defined. Another approach at giving an identity condition uses modal notions and says that the first sentence is a necessary truth while the second is not. This, however, raises the problem of giving a precise account of modal notions. Explaining modal claims in terms of analyticity, for example, ‘Necessarily humans are rational’ as explained by ‘"Humans are rational" is analytic’, will not do - since we have not defined ‘analytic’. Quine’s challenge is that one break out of this intensional circle and explain notions from the theory of meaning in more acceptable terms.

(2) He next rejects accounts of analyticity in terms of logical truth and synonymy. On this account a sentence is analytic if it is a synonymous instance of a logical truth, that is, ‘All bachelors are unmarried men’ is analytic in that it is derivable from the first-order logical truth ‘All bachelors are bachelors’ by putting a synonym ‘unmarried man’ for the second occurrence of ‘bachelor’. One account attempts to explain synonymy in terms of definition. However, the various forms of definition either presuppose synonymy or stipulate it; none explain it. Quine is sceptical of definitions or philosophical analysis when thought of as capturing or analysing some concept or meaning. Instead philosophical explication is thought of in terms of the theory of reference and scientific hypothesizing and thus again embodying the naturalistic theme of the continuity of science and philosophy. One does not capture ‘the meaning’ of an expression; one explicates or proposes a theory of the referential features one is interested in preserving.

(3) Another attempt to define synonymy asserts that two expressions are synonymous if they are interchangeable. But it is not enough to say expressions are synonymous when the interchange of the one with the other within extensional contexts does not change the truth value of the sentences involved. This has the unacceptable consequence that merely coextensive terms would be synonyms. To do better one has to require interchangeability within intensional contexts. However, this raises the problem of breaking out of the circle of intensional notions.

(4) The fourth approach is another of Carnap’s. It consists in constructing an artificial language and then defining ‘analytic’ for it. While it is possible to construct a language and specify that relative to it logic, mathematics and

such truths as ‘All bachelors are unmarried men’ and ‘Nothing is larger than itself’ are analytic, this language-relative specification of analyticity does not clarify matters. It does not help to be told that in one language, language 1 (artificial or otherwise), we have a list of sentences that are analytic 1, and that in another language, language 2, we have the list analytic 2 and so on. What we want of an explication of analyticity is an account of what analytic 1, analytic 2 and so on have in common. The appeal to artificial languages fails to provide this characterization. Moreover, the problem is precisely why ‘All bachelors are unmarried’ is on the list and ‘No bachelors are six-legged’ is not. To be told that a sentence is analytic because it is on a list (even the list of an artificial language) provides no real distinction.

(5) The last attempt to define analyticity that Quine considers appeals to the verification theory of meaning. According to this theory, ‘the meaning of a statement is the method of empirically confirming or infirming it’; ‘statements are synonymous if and only if they are alike in point of method of empirical confirmation or infirmation’ ([1953] 1961: 37). Though sympathetic towards the empiricist thrust of this theory Quine does not think it survives the holistic criticism of the dogma of reductionism.

Quine’s critique of the theory of meaning has amounted to a challenge to provide precise accounts of its notions. What counts as precise could take the form of reducing intensional notions to extensional ones. His criticisms of modal concepts has spurred a generation of responses in what is known as possible world semantics (see Modal logic, philosophical issues in §3), which in one of its variations can be seen as trying to provide a reduction of intensional modal notions via extensional metalinguistic truth conditions for modal statements. The success of this reduction is still challenged by Quinians (1981: 113-24). More in keeping with Quine’s challenge to explicate the theory of meaning is Davidson’s work on letting a Tarskian theory of truth serve as surrogate for a theory of meaning. Another way in which scepticism about the theory of meaning might be overcome would be by an empirical and behaviouristically constrained account of such notions. Carnap took up this challenge and sketched a programme for empirically identifying meanings by testing translation hypotheses, for example, a linguist’s hypotheses for translating the terms ‘Pferd’ from German to English as ‘horse’. Quine’s response was the topic of radical translation and his thesis of the indeterminacy of translation.

9 Indeterminacy of translation

How much of language is susceptible to empirical analysis? Like Carnap, Quine takes the case of linguists hypothesizing about translations as the subject matter for empirical inquiry. Both take as their data a native speaker’s response to appropriate stimuli. Quine introduces the concept of the stimulus meaning of a sentence for a person as the class of stimulations which would prompt them to assent to it. But Quine deals with the stimulus meaning of whole sentences, such as ‘This is a horse’, and not terms, such as ‘horse’. Quine’s linguist offers a hypothesis equating two sentences (one is the native’s and the other the linguist’s) and checks it against a native speaker’s assenting or dissenting to the native sentence in the presence of some nonverbal stimulus. Carnap considered translation for languages such as German and English which are known to have much in common. For Quine, the critical case is that of radical translation, that is, translations between languages that have little or nothing in common. Think of a linguist among some radically foreign tribe. The linguist observes a certain correlation between a native utterance of ‘Gavagai’ and the presence of rabbits, and proceeds to frame a hypothesis which equates ‘Gavagai’ and the one-word sentence ‘Rabbit’, short for ‘Here’s a rabbit’. The linguist could, on learning how to recognize the native’s assent and dissent, question the native by uttering ‘Gavagai’ when a rabbit appears and seeing whether the native assents. Carnap would presumably want this to count as evidence that ‘Gavagai’ and ‘Rabbit’ have the same meaning. But does the evidence really go that far? All that we have as data is the native’s expression and the rabbit stimulation. Quine claims that on these grounds one could equally well translate ‘Gavagai’ as ‘rabbit stage’ or ‘temporal part of a rabbit’ or something else. For wherever there are rabbit stimulations there are also rabbit-stage stimulations, and so on. On what basis, then, would one decide between these different translations? In the case of culturally similar languages one assumes a stock of more theoretical guides to translations, and thus one can ask the German whether all horses are *Pferde* and all *Pferde* are horses. In the case of radical translation, the linguist is not in a position to pose these more theoretical questions. At this point hypotheses less directly connected to the data - to the stimulus conditions - may be introduced by the linguist. These, which Quine calls analytical hypotheses, can be framed so as to do justice to quite different translations. Thus radical translation provides evidence for the thesis of the indeterminacy of translation (see Radical translation and radical interpretation §§2-5).

To illustrate this matter for the Gavagai case we must note that in order to ask the question 'Is this rabbit the same as that?' the linguist must have decided how to translate articles, pronouns, identity predicates and so on. To translate these sentences is to go far beyond the data provided by the stimuli and involves selecting from different sets of analytical hypotheses, that is, different possible manuals of translation. On one set of these we translate the question as 'Is this the same rabbit as that?', while on another as 'Is this rabbit stage of the same series as that?' Each of these translations is equally good, yet they are mutually incompatible. Since neither of these has any immediate connection with the Gavagai stimulation there is no way of deciding between them.

This indeterminacy provides further grounds for discrediting the notion of meaning. Philosophers have talked as if meanings are related to expressions in somewhat the same way as paintings in a museum are related to their labels. Quine dubs this 'the myth of the museum' (1969: 27). According to this view, two expressions are synonymous when they are related to a unique meaning, like two labels for the same painting. In the case of translation, one English expression is a translation of another in a different language when the two bear a relation to one and the same interlinguistic object which is their meaning. Quine is attempting to dislodge this model for thinking about language and to put in its place a more empirically based conception. According to the museum model, an expression has its meaning, pure and simple, and two synonymous expressions relate uniquely to one meaning which, as interlinguistic, is independent of the languages in which it is expressed. What Quine has shown is that it makes no sense to speak of language-independent meanings. Translation from one language to another is relative to a set of analytical hypotheses. There is no independent meaning of 'Gavagai' which the linguist can link to 'This is a rabbit' and not 'This is a rabbit stage'. The linguist is at best in a position of saying that 'Gavagai' and 'This is a rabbit' are synonymous relative to the assumption of certain analytical hypotheses. We have to study language in terms of linguistic behaviour in the face of stimulus conditions; in turn this behaviour must be interpreted in relation to more theoretical background assumptions. With the exception of observation sentences, we have at best relative notions of meaning (synonymy and analyticity), and these will not do the job philosophers have frequently assigned to them according to the myth of the museum.

Quine insists on behaviourism as the required method for studying language learning. He argues that we learn language by observing verbal behaviour and having our verbal behaviour reinforced by others. But there are naturalistic accounts of language learning which are scientifically respectable and not behaviourist (see Chomsky, N. §3). Yet although Quine insists on behaviourism as the method for studying and acquiring languages, he is not a behaviourist in psychology or the philosophy of mind. On the mind-body problem he endorses Davidson's anomalous monism - the view that our ways of speaking of the mental, for example, of perceptions and beliefs, cannot be stated in terms of the natural laws which govern the underlying physiological states, even though our mental states just are such states. Quine construes the matter so that mental ascriptions have a role in everyday life and the social sciences that cannot be precisely specified in purely physiological or physicalist terms.

ALEX ORENSTEIN

List of works

Quine, W.V. (1934) *A System of Logistic*, Cambridge, MA: Harvard University Press.(A revised version of Quine's dissertation.)

Quine, W.V. (1936) 'Truth by Convention', in O.H. Lee (ed.) *Philosophical Essays for A.N. Whitehead*, New York: Longmans.(Critique of attempts to justify logical and mathematical truth in some distinctively non-empirical way - for example, as grounded in conventions.)

Quine, W.V. (1937) 'New Foundations for Mathematical Logic', *American Mathematical Monthly* 44: 70-80.(One of Quine's most famous alternatives to issues in the foundations of mathematics such as Russell's paradox.)

Quine, W.V. (1940) *Mathematical Logic*, Cambridge, MA: Harvard University Press.(One of Quine's most systematic logic texts, including another alternative account of the foundation of mathematics.)

Quine, W.V. and Goodman, N. (1947) 'Steps Towards a Constructive Nominalism', *Journal of Symbolic Logic* 12: 97-122.(An early examination of the prospects for a nominalist programme in mathematics and its limitations.)

Quine, W.V. (1948) 'On What There Is', *Review of Metaphysics* 2: 21-38.(The classic statement of Quine's view on ontological commitment.)

Quine, W.V. (1951) 'Two Dogmas of Empiricism', *Philosophical Review* 60: 20-43.(Quine's classic critique of

the analytic-synthetic distinction and of reductionist-atomistic empiricism.)

Quine, W.V. (1953) *From a Logical Point of View*, Cambridge, MA: Harvard University Press, revised, 1961.(An early collection of some of his most famous essays, including ‘New Foundations for Mathematical Logic’, ‘On What There Is’ and ‘Two Dogmas of Empiricism’. The 1961 edition incorporates many important revisions.)

Quine, W.V. (1960a) ‘Carnap on Logical Truth’, *Synthèse* 12: 350-74.(Continues criticism of the attempt to give a distinctly linguistic justification of logical truth.)

Quine, W.V. (1960b) *Word and Object*, New York: Wiley & Sons.(A major source for Quine’s views on meaning, translation, reference, modality and propositional attitudes.)

Quine, W.V. (1966) *The Ways of Paradox and Other Essays*, New York: Random House.(A collection of essays on various topics, including ‘Truth by Convention’ and ‘Three Grades of Modal Involvement’.)

Quine, W.V. (1969) *Ontological Relativity and Other Essays*, New York: Columbia University Press.(Collection of essays including the title essay and others such as ‘Epistemology Naturalized’.)

Quine, W.V. and Ullian, J.S. (1970) *The Web of Belief*, New York: Random House.(An introduction to the scientific method from a Quinian perspective.)

Quine, W.V. (1974) *The Roots of Reference*, La Salle, IL: Open Court.(A Quinian, methodologically behaviourist account of how we get to talk about objects.)

Quine, W.V. (1981) *Theories and Things*, Cambridge, MA: Harvard University Press.(Essays, mainly from this period, on positing objects and what it means.)

Quine, W.V. (1985) *The Time of My Life: An Autobiography*, Cambridge, MA: MIT Press.(Quine’s very readable autobiography.)

Quine, W.V. (1986) *Philosophy of Logic*, Cambridge, MA: Harvard University Press.(An introduction to the subject via a discussion of truth, modalities and propositional attitudes, logic - its nature, scope and justification.)

Quine, W.V. (1987) *Quiddities*, Cambridge, MA: Harvard University Press.(Introduction to various philosophical topics via a dictionary format.)

Quine, W.V. (1992) *Pursuit of Truth*, Cambridge, MA: Harvard University Press.(A survey and update of Quine’s views on cognitive meaning, objective reference and the grounds of knowledge.)

Quine, W.V. (1995) *From Stimulus to Science*, Cambridge, MA: Harvard University Press.(A distinctive short tour of the history of philosophy, followed by an exploration of topics such as epistemology naturalized, reference, empirical content and the philosophy of mind.)

Rabelais, François (*c.*1483-1553)

Rabelais, a French humanist and comic writer of the Renaissance, is best known for his chronicles of Gargantua and Pantagruel, in which coarse popular humour, fine Lucianic irony and staggering erudition are uniquely blended, and which claim to reveal, first appearances notwithstanding, 'certain very high sacraments and dread mysteries, concerning not only our religion, but also our public and private life' ([1532-52] 1955: 38).

Rabelais has been subjected to the most contradictory interpretations and judgments. Like Erasmus, whom he admired, Rabelais was attacked in his own time by schismatic Protestants (most notably Calvin) and by reactionary Catholics (most notably the faculty of theology at Paris), as an obscene Lucianic atheist and a heretic. At the same time he was admired and supported by high-minded patrons including Francis I, the king's devout sister Marguerite de Navarre, and Cardinal Jean Du Bellay. Even today Rabelais' religion and philosophy are the subject of debate among scholars, while his work is known to non-specialists more for the 'Rabelaisian' ribaldry of a few pages than for the complex irony and profoundly humanistic design that characterize his works as a whole.

1 Intellectual orientation

Rabelais himself was a man of multiple talents and professions, prodigiously learned in all disciplines that were currently being transformed under the influence of humanism: classical languages (Latin, Greek, Hebrew), ancient and modern literatures, history, moral philosophy, medicine, law, theology. Son of a lawyer in Chinon, he served in the orders of St Francis and St Benedict before becoming a lay priest, a doctor and professor of medicine, an accomplished student of Roman law, an amateur biblical humanist, and a member of French diplomatic missions to the Holy See in the years leading up to the Gallican crisis (1534, 1535-6, 1547-9). His humanist preoccupations are clearly evident in the serious works he published in Latin and Greek in 1532. These include an annotated edition and Latin translation of medical treatises by Hippocrates and Galen, an edition of documents he took to be a will and a contract of sale dating from Roman Republican times, and an edition of a contemporary treatise on the topography of Ancient Rome. Equally revealing are several parodic almanacs Rabelais published in the vernacular, most notably the *Pantagrueline prognostication* (1533), in which astrology and prognostication generally are humorously debunked in the name of Christian scepticism.

Rabelais stated his intellectual loyalties explicitly in admiring letters to humanists like Guillaume Budé (1521) and Erasmus (1532). To the latter in particular he declared, addressing the aged humanist as his spiritual father and mother, that: 'whatever I am, whatever I am good for, it is to you alone that I owe it'. Rabelais' works in the vernacular give considerable substance to this extravagant claim, championing as they do Erasmian causes like the restoration of classical learning and the return to a non-doctrinal, eirenic, paleo-Christian church.

2 Early Works: *Pantagruel* and *Gargantua*

Rabelais' first two books, *Pantagruel* (1532) and *Gargantua* (*c.*1534), were published anonymously in Lyons under the anagrammatic pseudonym Alcofrybas Nasier. These vigorous mock epics relate the birth, education and 'horrific' exploits of two giant heroes drawn from popular tradition. Masquerading as penny chapbooks to be sold at the commercial fairs of Lyons, they adopt the format and superficial trappings of medieval popular literature in order to satirize all things medieval and represent the triumph of an enlightened Christian humanism over gothic darkness.

The principal focus of *Pantagruel* is political. Set in Utopia, the political non-place invented a mere sixteen years earlier by Thomas More (see Utopianism §1), and visibly inspired by pacificist writings like *Institutio principis christiani (Education of a Christian Prince)* (1516) by Erasmus (§3), *Pantagruel* narrates the failure of an imperialistic war of aggression. When Gargantua's realm is invaded by an usurping tyrant named Anarche (meaning 'non-rule') the eponymous hero repels the invaders, and inaugurates a new Golden Age of peace and harmony resembling Christ's kingdom of heaven (Matthew 20: 25-7 and 23: 12). He does this by abolishing the hierarchical political and religious institutions of the old order (empire and church). Pantagruel is prepared for this messianic role by a humanistic education. After a fruitless tour of the gothic universities he rejects the likes of Duns Scotus and Ockham and incorporates instead the entire curriculum of newly restored humanist disciplines,

described by Gargantua in a justly famous letter to his son ([1532-52] 1955: ch.8).

Appearing two years later, *Gargantua* rehearses the same basic plot as *Pantagruel* but in a more realistic and satirical mode. The unjust invader, Picrochole (which means ‘bitter bile’), resembles the Holy Roman Emperor Charles V in his incursions against Francis I. The scholastic old guard is represented by the ‘sophists’ of the Sorbonne, whose syllogistic illogic and wretched Latin are brilliantly parodied in a muddled speech by the unforgettable Master Janotus Bragmardo (see Major, J. §4). To these familiar themes *Gargantua* adds a sustained attack against monasticism, focusing on what Erasmus called the *constitutiones humanae* of the modern church (that is, traditions and practices unauthorized by Scripture). The most sympathetic character of the book is an anti-monk named Frère Jean des Entommeures, whose febrile activity and good-natured spontaneity are favourably contrasted with the monastic ideal of a contemplative life governed by rules and regulations. The book concludes with the founding of a utopian anti-monastery, the Abbaye de Thélème, in which the Benedictine Rule is abolished in favour of the Pauline principle of Christian freedom, expressed in the single non-rule, ‘Fay ce que vouldras’ (‘Do as you wish’).

3 Late works: *Tiers Livre* and *Quart Livre*

Many years later Rabelais wrote a sequel to *Pantagruel*, the *Tiers Livre (Third Book of Pantagruel)* (1546), followed by a sequel to the sequel, the *Quart Livre (Fourth Book of Pantagruel)* (1552). Published in Paris under the author’s own name, printed in beautiful Roman type and humanistic format, these more mature works are of a very different character. Massive humanistic learning overwhelms attenuated vestiges of popular humour and comic effects depend less on the reader’s recognition of well-known biblical and Virgilian tags, as before, than on a good first-hand knowledge of works of moral philosophy by Plutarch and Lucian, Cicero and Seneca, as well as the Hebrew Bible, the Greek New Testament, Pliny’s *Natural History* and the Justinian *Digest*. The sequels relate a pseudo-Socratic quest undertaken by Pantagruel’s foolish companion, Panurge. In both books the quest ends in failure and appears to serve chiefly as a loose structuring device for an open-ended series of episodes in which political, theological and philosophical ideologies and institutions are brilliantly satirized.

The focal character of the *Tiers Livre*, Panurge, is a sophistical egotist first seen justifying his profligacy by praising debts as the *anima mundi* in terms borrowed directly from Ficino’s *De amore (On Love)* (1469) (see Ficino, M. §4). Suspended between the desire to take a wife and the fear of being cuckolded, he tries in vain throughout the book to decide whether or not to marry. Whereas the Socratic Pantagruel would have him do this simply by knowing his own will, the gnostic Panurge insists that he must first know things above and beyond himself, believing that such knowledge will allow him to eliminate future contingents. His misguided quest leads him to consult burlesque sources of divination as well as experts in various fields of learning, none of which provides the certainty he seeks. In the lengthy discussions surrounding many of these consultations Pantagruel speaks the language of Neoplatonism in such a way as to mock the Hermetic tendencies of his wayward companion. Panurge’s thirteen consultants include a sinister astrologer, Her Trippa, in whom many have seen a caricature of Henricus Cornelius Agrippa and an exasperatingly elusive philosopher, Trouillogan, in whom Rabelais ridicules ‘ephectic’ Pyrrhonians a full decade and a half before the works of Sextus Empiricus first appeared in print.

The *Quart Livre* prolongs the quest of the *Tiers Livre* in a fantastical sea voyage to Cathay where Panurge hopes to consult the oracle of Bacbuc, the Holy Bottle. But Panurge’s personal dilemma is soon displaced by the political and religious crises of contemporary Christendom as the principal focus of the continuation. Modelled roughly on Lucian’s *True History* and profoundly influenced by Plutarch’s *On the Obsolescence of Oracles*, this bitter odyssey narrates Pantagruel’s encounters with the inhabitants of fourteen islands, which satirize the social and political institutions of modern Europe. The harshest episodes condemn the Council of Trent and the doctrines and practices it was even then legislating as dogma. The un-Christian fanaticism and intransigence of both Catholics and Protestants is a recurring theme.

The *Quart Livre* ends even more abruptly than the *Tiers Livre*, far from its ostensible goal. This deliberately non-teleological structure was so unsettling that it provoked an anonymous editor to publish an apocryphal, posthumous *Cinquiesme Livre (Fifth Book of Pantagruel)* (1564), which concludes with the Holy Bottle and the oracular word (‘Trinch’) vainly sought by Panurge in the *Quart Livre*. Although this final revelation completes Panurge’s personal quest it adds nothing to the meaning of the preceding books and seriously detracts from their

formal and ideological coherence.

EDWIN M. DUVAL

List of works

Rabelais, F. (*c*.1483-1553) *The Complete Works of François Rabelais*, trans. D. Frame, Berkeley and Los Angeles, CA: University of California Press, 1991.(The only English translation that includes minor works and letters, all helpfully annotated by the translator and R.C. La Charité. The letters to Budé (1521) and Erasmus (1532) and the *Pantagrueline prognostication* (1533) appear in this edition, as well as the five books of Gargantua and Pantagruel.)

Rabelais, F. (*c*.1483-1553) *Oeuvres complètes*, ed. M. Huchon, Bibliothèque de la Pléiade, Paris: Gallimard, 1994.(The complete works in French and Latin, superbly edited and annotated by the leading expert on Rabelais' language and the evolution of his text. Destined to supersede the standard but incomplete edition begun by Abel Lefranc in 1913. Contains a useful chronology and a full bibliography of recent books on Rabelais.)

Rabelais, F. (1532-52) *Gargantua and Pantagruel*, trans. J.M. Cohen, London and New York: Penguin, 1955. (The most accessible and faithful of modern English versions, unfortunately virtually unannotated. Like all editions includes the posthumous *Cinquiesme Livre* (1564) along with the authentic four books, *Pantagruel* (1532), *Gargantua* (*c*.1534), *Tiers Livre* (1546) and *Quart Livre* (1552).)

References and further reading

Cooper, R. (1991) *Rabelais et l'Italie*, Études Rabelaisiennes, Geneva: Droz.(Presents most extant documents pertaining to Rabelais' personal and civic life, expertly edited. Introduction helps to fill some gaps in our sketchy knowledge of Rabelais' life and partially fills the need for an up-to-date biography.)

Defaux, G. (1973) *Pantagruel et les sophistes: Contribution à l'histoire de l'humanisme chrétien au XVIe siècle*, The Hague: Nijhoff.(An extremely erudite analysis of the conflict between scholasticism and Christian scepticism in Rabelais' works, especially *Pantagruel*. An important, rewarding study, but hard reading for those with little Latin.)

Desrosiers-Bonin, D. (1992) *Rabelais et l'humanisme civil*, Études Rabelaisiennes, Geneva: Droz.(Insightful, thorough thematic treatment of the ethical and political dimensions of Rabelais' works. Includes a complete bibliography of modern Rabelais scholarship up to 1990.)

Duval, E.M. (1991) *The Design of Rabelais's Pantagruel*, New Haven, CT and London: Yale University Press. (Demonstrates the formal and ideological coherence of Rabelais' first book as they are revealed through an overarching epic and messianic pattern.)

Duval, E.M. (1997) *The Design of Rabelais's Tiers Livre de Pantagruel*, Études Rabelaisiennes, Geneva: Droz. (Discovers the coherence and intention of Rabelais' most ambiguous book in the hero's ironic design for his companion and in the author's corresponding design for his reader, both of which turn on the oracular 'Know thyself' uttered by Panurge at the centre of a symmetrically-ordered work.)

Duval, E.M. (1998) *The Design of Rabelais's Quart Livre de Pantagruel*, Études Rabelaisiennes, Geneva: Droz. (Examines the religious basis for Rabelais' critique of the ideologies and institutions of sixteenth-century Europe, and the nature of Pantagruel's ethical stance in confronting them.)

Febvre, L. (1982) *The Problem of Unbelief in the Sixteenth Century: The Religion of Rabelais*, trans. B. Gottlieb, Cambridge, MA: Harvard University Press.(Translation of a book by the great Annales School historian, first published in 1942 to refute the then current view that Rabelais was a rationalist and an atheist. A milestone in Rabelais scholarship still useful for its analysis of Rabelais' intellectual and religious culture and for background on humanist circles in Lyons.)

Screech, M.A. (1959) *L'Évangélisme de Rabelais: Aspects de la satire religieuse au seizième siècle*, trans. by the author as *Rabelais and the Challenge of the Gospel: Evangelism, Reformation, Dissent*, Baden-Baden: Koerner, 1992.(Treats theological questions like the nature of faith, the efficacy of works, predestination and freedom of the will, and so on, according to Rabelais. Occasionally mistakes the intention of the text by reading it as a theological treatise.)

Screech, M.A. (1979) *Rabelais*, London, Duckworth and Ithaca, NY: Cornell University Press. (A useful, accessible episode-by-episode commentary on all of Rabelais' literary works, distilling the fruits of a lifetime of scholarship by the most learned of modern Rabelais scholars.)

Weinberg, F.M. (1972) *The Wine and the Will: Rabelais's Bacchic Christianity*, Detroit, MI: Wayne State University Press.(Analyses the ubiquitous wine motif in terms of a syncretistic fusing of Bacchic mysteries and Christian eucharist.)

Race, theories of

The first theories of race were attempts to explain why the peoples of Europe (or sometimes particular peoples within Europe) had developed a higher civilization than the peoples of other regions. They attributed inequality in development to different biological inheritance, undervaluing the importance of the learning process. Between the world wars social scientists demonstrated how many apparently natural differences, and attitudes towards other groups, were not inherited but learned behaviour. They asked instead why people should entertain false ideas about members of other groups. As the twentieth century comes to an end, it is claimed on the one hand that processes of racial group formation can be explained in the same terms as those used for explaining group phenomena in general. On the other hand it is maintained that the only possible theories are those explaining why, in particular societies and at particular times, racism assumes a given form.

1 Unequal development

The word race entered west European languages in the sixteenth century to designate a set of humans of common ancestry. The end of the eighteenth century saw the first attempts to utilize it as a scientific concept. These ultimately failed, but much confusion was generated by the lack of clarity in its scientific use and by the interaction between popular and scientific usage. The French anatomist Cuvier in 1817 divided *Homo sapiens* into three subspecies (or varieties) which he called races: they were Caucasians, Mongolians and Ethiopians. He maintained that differences in human physique produced differences in culture and mental quality. This explained why whites had gained dominion over the world and made the most rapid progress in the sciences. ‘Yellows’ were less advanced, and blacks degraded. So race was used as a taxon, but if it meant the same as subspecies it was redundant. It was also employed as an *explanans* of unequal development. At much the same time the idiom of race was popularized in historical novels, notably in Sir Walter Scott’s description of Normans and Saxons as races in his best-selling *Ivanhoe* (1820). Racial designations were used as a way of identifying group differences within Europe that was later extended to describe differences between Europeans and the peoples of other regions colonized by Europeans.

Any understanding of the causes of variation within the human species in the pre-Darwinian era was bedevilled by the near-impossibility of explaining how that variation could have come about if, as was generally believed, humanity had descended from Adam and Eve in the space of some six thousand years. One answer was the claim that humanity consisted of a limited number of permanent racial types (as argued by Charles Hamilton Smith in England, Robert Knox in Scotland, Arthur de Gobineau in France, J.C. Nott and G.R. Gliddon in the USA, Karl Vogt in Germany). This doctrine has often been called scientific racism. Its exponents tended to equate race with species and claimed that it constituted a scientific explanation of human history.

Darwin’s theory of natural selection was applied to human affairs by the eugenists and by writers such as Sir Arthur Keith. Their arguments in certain respects prefigured modern sociobiology. They presented races as units in the course of evolution which developed their distinctiveness by in-breeding. Racial prejudice was seen as an inherited character that helped them do this. This has also been seen as scientific racism, but whereas the typological theory looked to the past in assuming that there had once been pure races, the selectionist theory looked to the future in presenting ethnic and national groups as prospective species.

The further development of Darwinian theory put an end to the notion of race as an *explanans* of human history. If one publication marks the transition, it is *We Europeans* (1935) by Sir Julian Huxley and A.C. Haddon. This separated human physical variation, as an *explanandum* to be explained by population genetics, from the variation between national groups (now named ethnic groups) to be addressed by historians and social scientists (see Evolutionary theory and social science).

2 Early social science

Not until the 1920s was there evidence that racial prejudice was a form of learned rather than inherited behaviour. How then were the physical differences that people in western Europe and North America called ‘racial’ used to construct social categories?

The ecological theory developed by Robert E. Park in Chicago maintained that migration brought distinctive

peoples into contact; competition made them conscious of what distinguished them, and those in a superior status developed prejudice as a defensive reaction.

The Freudian theory maintained that social life built up frustration which individuals released on to scapegoats in the form of displaced aggression; this added to the direct aggression that sprang from the conflict of interests.

The first empirical studies of the relations between blacks and whites in the USA of the 1930s were cast in a structural-functionalist framework. US society was said to be founded on distinctive values that stressed the social equality of citizens. Racial discrimination conflicted with these values and generated an ‘American dilemma’.

This orthodoxy was attacked most vigorously in *Caste, Class and Race* (1948) by Oliver Cromwell Cox, a black Trinidad-born sociologist. He contended that as European capitalism expanded into territories where natural resources were abundant, demand increased for labour, especially unfree labour. So beliefs justifying black subordination were built into the structure of capitalist societies, dividing white from black workers. Cox distinguished racism and anti-Semitism as distinct social forms. The former justified exploitation. The latter was directed to the conversion, expulsion or eradication of the alien group. That the two might share a common psychological component was irrelevant.

Many subsequent writers have similarly chosen to start from postulates about power relations within and between states. While conceding that in some societies the main conflicts derived from the relation of groups to the means of production, Leo Kuper maintained that there were states (like apartheid South Africa) in which political power influenced the relation to the means of production much more than any influence in the reverse direction. These were ‘plural societies’ in which racial conflict pre-empted or preceded class conflict.

3 Recent social science

Recent theoretical writing is at one in recognizing the political significance of race as a folk concept underlying group boundaries and in denying that this concept has any value for the explanation of why humans draw racial boundaries in particular ways. To simplify what can otherwise be a confusing picture, it can be helpful to focus upon the sharp division of opinion about what are the most important *explananda* and about the kind of *explanantia* to be sought. These are expressed in two ‘problematics’ (meaning by this sets of questions of interest to scholars who share views about the best ways to answer the questions). The racial discrimination problematic (a revised version of the frequently-criticized race relations problematic) holds that the attitudes and behaviour which in popular speech are called racial are to be explained in the same terms as other forms of attitude and behaviour. The racism problematic, by contrast, holds that there is a distinctive historical phenomenon known as racism that has to be seen for itself and related to the social processes that produce it. Underlying these contentions are two contrasting epistemologies; there is no agreement on the best names for these, though the writer has called them Kant-inspired and Hegel-inspired.

The first problematic is primarily concerned with the causes of racial discrimination as a feature of individual behaviour. It holds that discrimination, like crime, is a normal feature of every kind of society. Discrimination is not necessarily unlawful or immoral, and individuals are to be held morally responsible for any social distinctions they draw. Because it starts from the individual, this approach leads to a rational choice theory that borrows from neoclassical economics and the analysis of the means-end relationship in sociology. The name has led some into assuming that it is a theory of rational choices alone, whereas the theory takes rationality (or optimization) purely as a criterion against which to assess the consequences of choices of whatever motivation or character (see Rational choice theory). The attitudes and behaviour that are popularly called racial are then explained as the product of shared tastes or values which individuals seek to satisfy in situations of scarcity and constraint. Outward differences, like those which are called racial, may be used to identify persons as belonging to particular social categories. A person’s appearance may create an expectation that they will possess or lack some social quality. Through such expectations social inequalities in one generation may be transmitted to succeeding generations. This approach attempts, within a single conceptual framework, to analyse processes of group inclusion and exclusion based upon ethnic origin in all historical periods and geographical regions.

The contrasting problematic is primarily concerned with racism as a pathological feature of society that generates structural and ideological pressures upon individuals, thereby diminishing the degree of their personal responsibility for any discriminatory action. Its starting point is with the collectivity, confining the analysis of

group inclusion and exclusion to particular societies and their spheres of influence. The utility for research of the postulate that racism is manifested in changing forms is dependent upon the reliability of the method for identifying what lies behind the form. The political dimension of the problem was illustrated in 1975 when the UN General Assembly resolved that ‘Zionism is a form of racism and racial discrimination’ (a resolution revoked in 1991). Whether Zionism is such a form depends upon the definitions of Zionism and racism.

The approach from racial discrimination follows Kant’s view of the Copernican revolution in science. The observer does not seek to comprehend objects in their entirety as things in themselves, but, by standing apart from them, to develop concepts that will help explain selected features of the observations. Definitions have to be adapted to research methods (see Kant, I. §6). The approach from racism follows Hegel’s view of the observer as part of the world they study, but able to ascertain the principles underlying the development of that world and to reach a knowledge validated by history (see Hegel, G.W.F. §8). Definitions are sought that will express the true nature of objects. There is a fundamental difference of opinion about the kinds of knowledge that are possible and the task of the social scientist.

French sociologists have recently revived and reformulated one of Cox’s arguments. They contend that whereas racial ideology in Europe used to follow a logic of inferiorization and exploitation, it now follows a logic of differentiation directed to the expulsion or destruction of groups perceived as alien. The structures of industrial society based upon stratification and the welfare state have been weakened. In the West the old nationalism has lost its appeal so that people have been turning to regional, ethnic, religious and life-style identities. These conditions stimulate racist exclusions. In the UK and North America, as in France, it is now said to be necessary to distinguish a variety of racisms that are expressed in coded language. Crucially, they can produce a racist effect while denying that this effect is the result of racism. For example, certain arguments about defending a national way of life against the pressures of immigration have been described as coded expressions of racist sentiment. ‘Race’ is said to be a political construct and the sociologist’s choice of an *explanandum* a political decision. But there remains the problem of how to delimit the number of possible racisms. For example, the Catholic Church contends that *in vitro* fertilization and genetic manipulation could give rise to a new form of racism; others might argue that whether or not such possibilities are matters of concern, their origins are not those of racial ideology. Since racism is assumed to be a hidden essence, there is no sure way of establishing any cause-and-effect relationship.

Racial differentiation has been a subject for research in other social sciences. In social psychology there is now no distinctive branch of ‘racial’ theory. Racial distinctions are explained by reference to the principles used in accounting for other forms of group behaviour, such as attitudes, attributions, identity, and so on. Geographers have studied processes of racial segregation, including the spatial dimension to the emergence of new identities based upon racial or ethnic origin. Political scientists have studied the influence of racial identification upon voting behaviour and the ways in which racial problems and policies are handled by national and international political institutions. Since the collapse of Soviet control over eastern Europe many older ethnic conflicts have reappeared, so that for some fields of research theories of racial or ethnic tensions have to entail theories of nationalism.

Radbruch, Gustav (1878-1949)

Gustav Radbruch is an emblematic figure in twentieth-century German legal philosophy and legal science. His particular blending of legal philosopher, dogmatist and politician, and his personal history, interwoven with the tragedy of the Weimar Republic and the rebirth of a democratic Germany after the Nazi horror, have given him special prestige and influence on both constitutional and ordinary jurisprudence in Germany. Some of Radbruch's theses, like the one in his well-known article 'Gesetzliches Unrecht und übergesetzliches Recht' (1946 - translatable as 'Statutory Non-law and Suprastatutory Law'), remain highly topical in German universities and courts.

Radbruch was born in Lübeck to a family of the mercantile bourgeoisie. He completed high school there, and entered the Munich law faculty in 1898, later studying also in Leipzig and Berlin. In Berlin he was a pupil of Franz von Liszt, probably the most influential scholar of criminal law in the new unitary German state, who upheld the line of liberal thought inaugurated by P.A. Feuerbach. Under Liszt's guidance, Radbruch took his doctorate in 1902. The following year, at Heidelberg University, Radbruch secured his *Habilitation* with a study on the relevance of the concept of action to the doctrine of criminal law. He filled various teaching posts between 1906 and 1914, took part in the First World War, and in 1919 secured a chair in criminal law at the University of Kiel.

In 1920 he was elected to the Reichstag, the German parliament, as a socialist member, and in 1921 became Minister of Justice in the Wirth cabinet, subsequently serving again as a minister in the first and second Stresemann cabinets. In November 1923, after Stresemann's withdrawal, he went back to Kiel University, where he stayed till autumn 1926 when he was called to a chair at Heidelberg University. Shortly after Hitler came to power, in May 1933, he was among the first university teachers to be removed from their posts on political grounds. In the twelve years of the Nazi regime, Radbruch retreated to the so-called *innere Emigration*, condemned to silence in his own country even though he did not leave it, devoting himself to historical and humanistic studies and publishing abroad. In September 1945, after the Nazis' defeat, he was appointed Dean of Law at Heidelberg, returning to teaching with renewed enthusiasm.

Radbruch's oeuvre is bracketed by two works, the book *Grundzüge der Rechtsphilosophie* (1914, with a definitive revised edition in 1932) and the 'Gesetzliches Unrecht und übergesetzliches Recht' ('Statutory Non-law and Suprastatutory Law') of 1946 (see Radbruch 1973). This article overturns the main thesis of the *Grundzüge*, namely a radically noncognitivist meta-ethical position, denying claims to knowledge or to objective rightness in moral values (see Moral judgment §1). For such an ethical relativism, to which all possible moralities seem acceptable, positive law is independent of moral values. The point is then to arrive at a formula or a conception of positive law not committed a priori to any ethical position, but permitting all of them. Radbruch considered this possible only if a positivistic conception of law is assumed. Here, then, as is also the case *mutatis mutandis* in Hans Kelsen's work, the endpoint of ethical relativism is legal positivism (see Kelsen, H.; Legal positivism §§1, 2).

Noncognitivism is also used by Radbruch to found or justify democracy: if no conception of any faction is capable of proof, then every conception should be fought from the viewpoint of an opposite conception; but since none of them can be refuted, each of them ought accordingly to be respected even within the viewpoint of the opposing conception (Radbruch 1934). Although he maintained that the concept of law 'is a cultural concept, that is, the concept of a reality oriented to values, which has the object of serving a value' (Radbruch 1973: 29), for Radbruch, at least until 1933, a law whose promulgation is formally and procedurally correct is valid and binding even where its content is morally reprehensible. This conclusion has, however, also a moral basis, grounded in the idea of legal certainty: 'However unjust the law may become in its content, it always, from its mere existence, meets one aim: that of legal certainty' (Radbruch 1914: 183).

Experience of the Nazi horror changed Radbruch's view radically. First and foremost, he accused legal positivism, understood more as a psychological attitude than as a legal philosophical doctrine, of having prepared, aided, or failed to obstruct the affirmation of Nazism. Jurists, accustomed to the motto '*Gesetz ist Gesetz*', that is, to regard any duly enacted statute as valid and binding law, however it be promulgated, were incapable of showing resistance to Hitler's injustice and despotism. There must therefore be a change of attitude by jurists, starting from,

or at least not neglecting, requirements of substantive justice, so that - this is the 'Radbruch formula' still applied by the German Constitutional Court - where a formally valid law proves intolerably unjust, it is no longer to be regarded as valid or binding. The 'Radbruch formula' breaks down into three parts: (1) first, it is asserted that in general positive law prevails over substantive requirements of justice, even when, while formally valid, it is unjust and irrational; (2) this primacy stops at breaches of principles of justice that are of intolerable proportions; (3) intolerable breaches of justice exist where the positive law explicitly and systematically does not have as its goal the realization or pursuit of aims of justice, and especially where the principles of formal equality (the equal treatment of equal cases) are deliberately and constantly ignored (see Justice, equity and law §1; Law and morality §1).

In German culture between the nineteenth and twentieth centuries, in particular in the stormy years of the Weimar Republic, Radbruch represents the enlightened, democratic tradition, all too rare in those times among German philosophers and jurists, often seduced by irrationalist, communitarian and authoritarian slogans. It is the Germany of Kant and of Anselm Feuerbach, the *Zivilisation* of reason and of rights, whose courageous interpreter he is. 'The expression of a spirit that has become profoundly sterile' was how he was contemptuously dismissed by the Nazi Karl Larenz. But in the end it is Radbruch's, not Larenz's, spirit that has proved fertile.

Radhakrishnan, Sarvepalli (1888-1975)

As a modern interpreter of Indian thought to Western scholars and a major influence on later Indian thinkers, Sarvepalli Radhakrishnan's teaching, writing and worldwide lecturing introduced the West to Indian religion and philosophy as essentially an all-inclusive monism. He was actively committed to participation in Indian and international society as an educator, statesman and leader of the Indian republic and defended Hinduism against Western critics as essentially tolerant, world-affirming, progressive and socially and politically conscious. Radhakrishnan's neo-Advaita *was based on one major strand of Indian monism with modifications based on assumptions from his education in Christian institutions. While maintaining that the Absolute is identical with one's true self, he emphasized the reality of the universe. The truly religious person, he argued, does not flee the world but withdraws to attain personal realization and returns to apply the insight thereby gained to better society.*

1 Life and influences

Sarvepalli Radhakrishnan's life was that of a philosopher, definer and apologist for Hinduism and an active educator, statesman and world figure. Born in 1888 in south India, he was educated at Christian missionary schools. He received his BA and MA in philosophy from Madras Christian College. He studied under the Christian missionary and ethicist A.G. Hogg (1856-1931) who was a student at Edinburgh University of A.S. Pringle-Pattison and was influenced by A. Ritschl's school of German theology. Trained as an ethicist, Radhakrishnan emerged with the ethical concern of his teachers, but argued that this concern was found in his own tradition, which he traced back to early Indian scriptures and called Vedānta. The major influence in his definition of his tradition was the writings of the modern Indian leader Swami Vivekananda (see Ramakrishna movement), whose response to critics and definition of Hinduism resolved a number of Radhakrishnan's existential dilemmas. Radhakrishnan chose it as his own definition and devoted his thinking to explicating it as a philosophy and proclaiming it in his life and writings.

After a number of university appointments in south India, Radhakrishnan was appointed in 1921 to the most prestigious philosophical position in India, the King George V Chair of Mental and Moral Science of Calcutta University. From 1936 to 1941 he was the Spalding Professor of Eastern Religions and Ethics at Oxford University. His many posts include chief executive officer at a number of Indian universities, president of the executive board of UNESCO, a member of independent India's constituent assembly, India's second ambassador to the Soviet Union, vice president of India (1952-62) and president of India (1962-7). He lectured throughout the world, retired in 1967 and died in April 1975, having written over three dozen books. These included commentaries on four Indian religious texts and over one hundred articles on philosophy and religion.

2 Metaphysics

In his two-volume *Indian Philosophy* (1923) Radhakrishnan surveys and evaluates the major Indian philosophical traditions, but from his early writings he clearly identifies his approach and evaluation of others with the tradition of Advaita Vedānta of the eighth-century thinker Śaōkara and the early Indian scriptures called the Upaniṣads which, he believes, show evidence of that tradition. Thus, reality is ultimately a unity in which the One is the indescribable, impersonal Absolute, Brahman (see Brahman; Monism, Indian). This One is also the true self, a state of pure consciousness which is a subject rather than an object to us. In traditional terms it is *saccidānanda*, being itself, pure consciousness and unlimited bliss. Knowledge of this One is possible through rational analysis of the empirical data, but certainty comes from an intuitive, immediate awareness of Brahman. Science gradually confirms what religions have intuitively understood. This monism does not negate the world, Radhakrishnan insisted, and Śaōkara has thus been gravely misunderstood when interpreted as teaching that the world is an illusion. When Śaōkara declared all but the unqualified Brahman to be *māyā*, he meant that the world's reality is not independent, for its cause is Brahman. Only Brahman is independently real and the world is one particular manifestation of Brahman, although the actual nature of the relationship between the world and Brahman is logically inconceivable. Radhakrishnan's concern is to affirm the reality of a place in which to live the ethical life and to embrace the universe itself as a cosmic process which has meaning and value. This position he calls 'idealism' (see Idealism).

Others have understood the Absolute to be a personal, divine being. This is not a false understanding, he asserted, but a reference to the impersonal Absolute in its relationship to the world. The gods of India are personifications and symbols of the Absolute and three major deities form the *trimūrti*, the three forms of the One Brahman, at times called the Hindu Trinity. Brahma is the Divine as creator, Vishnu as preserver and Shiva as destroyer.

3 Ethics

The goal of human existence, Radhakrishnan asserts, is not a flight from this world for mere personal salvation. Hinduism has been falsely accused of teaching this. Human beings find themselves in ignorance in the rounds of karma and rebirth, but karma is not a mechanical principle; it is an ethical one. It should not be understood fatalistically, as has often been the popular understanding in India. Although actions from past lives have conditioned the present life, humanity can overcome the conditioning through choosing to live the good life. There is no mercy or grace to be sought, only human responsibility. The goal of Hinduism and true religion is *sarvamukti*, the liberation of all. One may withdraw from life in the world for a period to attain an intuitive experience of the One. However, in the spirit of the Buddhist *bodhisattva*, who refuses to enter liberation until all beings are brought in together (see Duty and virtue, Indian conceptions of §3), the realized individual returns to the world, with the insights gained thereby, to provide a religious, moral and social influence which leads all to liberation. Since all human beings are one in spirit, sacrifice and a life of service follows. Radhakrishnan chooses the *Bhagavad Gītā* (second century BC) with its call to an active lifestyle, as his major support for an ethic of unselfish action.

He does not reject the class system in India, but argues that its correct understanding is as the ordering of society, which he understands to be more like an organism. The four classes are necessary for the life of society, but these divisions are not based on birth but on ethical personality types without one being any higher, purer or more important than another. Therefore, in Radhakrishnan's opinion, this is not the corrupted system of castes found in contemporary India. The intention of the system is to solve the problem of race in India by allowing separate divisions without extermination or subordination.

4 Inclusivism

Radhakrishnan argued for the future of religion against those who proclaimed its modern irrelevance. That future faith, he said, must be consistent with the discoveries and experiential approach of science, morally active so as to solve the world's social problems and inclusive of all the world's religious viewpoints so as to promote world unity. In his later writings he advocated this 'religion of the spirit' or 'spiritual religion' which he defined in terms similar to his earlier definitions of Vedānta and Hinduism.

Radhakrishnan made religious tolerance a major theme of his work, defining it not as merely bearing with others, but as a hierarchic, subordinating inclusivism. He affirmed the truth of religious positions in terms of a hierarchy. He believed in an impersonal Absolute, identical with the self to be the highest understanding of reality as it is and that theistic positions of the highest reality as a Divine being are subordinate doctrinal understandings. These should be accepted as expressions which are relative to the historical environment of the believer (see Religious pluralism; Toleration).

Radhakrishnan quoted widely from the literature of the world's religions to support his contention that at the heart of all religions is a common religious experience which is understood differently by the religions according to their particular cumulative traditions. Hinduism, he argued, understands this best and allows for a variety of doctrinal interpretations. However, the nondual experience of the impersonal Absolute as the true Self within is, in fact, the nature of that experience.

As spokesman for the Indian state, Radhakrishnan argued that this understanding of monistic idealism provided the basis for democracy. The individual's value is rooted in its essential identity with the Absolute. Applied to economics, Radhakrishnan spoke in general terms of the value of a socialism which is 'economic democracy'. Likewise, the correct understanding of political secularism was not the indifference or rejection of religion by the state, but a nonsectarianism which affirms the essence of all religions. That essence is the 'religion of the spirit', he affirmed. Radhakrishnan's general approach to political thought and his public role as a detached teacher while president of India, positioned him as the ideal public *rājaguru*, the traditional scholar-teacher of the king, for

India's first two prime ministers, Jawaharlal Nehru and Lal Bahadur Shastri.

Radical translation and radical interpretation

Radical translation *is the setting of a thought experiment conceived by W.V. Quine in the late 1950s. In that setting a linguist undertakes to translate into English some hitherto unknown language - one which is neither historically nor culturally linked to any known language. It is further supposed that the linguist has no access to bilinguals versed in the two languages, English and (what Quine called) 'Jungle'. Thus, the only empirical data the linguist has to go on in constructing a 'Jungle-to-English' translation manual are instances of the native speakers' behaviour in publicly recognizable circumstances. Reflecting upon the fragmentary nature of these data, Quine draws the following conclusions:*

(1) It is very likely that the theoretical sentences of 'Jungle' can be translated as wholes into English in incompatible yet equally acceptable ways. In other words, translation of theoretical sentences is indeterminate. On the assumption that a sentence and its translation share the same meaning, the import of indeterminacy of translation is indeterminacy of meaning: the meanings of theoretical sentences of natural languages are not fixed by empirical data. The fact is, the radical translator is bound to impose about as much meaning as they discover. This result (together with the dictum 'no entity without identity') undermines the idea that propositions are meanings of sentences.
(2) Neither the question of which 'Jungle' expressions are to count as terms nor the question of what object(s), if any, a 'Jungle' term refers to can be answered by appealing merely to the empirical data. In short, the empirical data do not fix reference.

The idea of radical interpretation *was developed by Donald Davidson in the 1960s and 1970s as a modification and extension of Quine's idea of radical translation. Quine is concerned with the extent to which empirical data determine the meanings of sentences of a natural language. In the setting of radical interpretation, Davidson is concerned with a different question, the question of what a person could know that would enable them to interpret another's language. For example, what could one know that would enable the interpretation of the German sentence 'Es regnet' as meaning that it is raining? The knowledge required for interpretation differs from the knowledge required for translation, for one could know that 'Es regnet' is translated as 'Il pleut' without knowing the meaning (the interpretation) of either sentence. Beginning with the knowledge that the native speaker holds certain sentences true when in certain publicly recognizable circumstances, Davidson's radical interpreter strives to understand the meanings of those sentences. Davidson argues that this scenario reveals that interpretation centres on one's having knowledge comparable to an empirically verified, finitely based, recursive specification of the truth-conditions for an infinity of sentences - a Tarski-like truth theory. Thus, Quine's radical translation and Davidson's radical interpretation should not be regarded as competitors, for although the methodologies employed in the two contexts are similar, the two contexts are designed to answer different questions. Moreover, interpretation is broader than translation; sentences that cannot be translated can still be interpreted.*

1 Radical translation

Suppose that children, in the normal course of events, acquire their native tongue (for example, English) by observing their parents and others talking in publicly observable circumstances. A corollary of this common sense supposition is that whatever there is to linguistic meaning can be manifested in behaviour in publicly observable circumstances. However, one might ask, just how far do empirical data go toward fixing the meanings of the sentences being spoken? Quine's thought experiment of radical translation is designed to answer this question.

In the context of radical translation, the field linguist sets out to construct a manual for translating the newly discovered language of 'Jungle' into English. Of course, the linguist has a prior knowledge of English, and will exploit that knowledge in constructing a 'Jungle-to-English' translation manual. Obviously, a child learning a first language has no prior language to exploit. So, there is this fundamental difference in psychological readiness to learn 'Jungle' between the linguist and the child of native-speakers of the language. However, this difference does not affect the central fact that the ultimate empirical data available to both linguist and child are the same: facts about behaviour. The poverty of these ultimate data is what the context of radical translation is meant to bring out.

2 Indeterminacy of translation

The primary reference for indeterminacy of translation is ‘Translation and Meaning’, the second chapter of Quine’s *Word and Object* (1960). According to that account, the linguist first compiles a list of phonemes of the native-speakers’ language (which Quine dubbed ‘Jungle’), and then they settle on some expressions used by native speakers for assent and dissent.

A rabbit scurries by; the native speaker utters ‘Gavagai’. Having noticed the rabbit, and that the native speaker noticed it too, and suspecting that the rabbit probably prompted the native speaker’s utterance of ‘Gavagai’, the linguist tentatively enters into their ‘Jungle-to-English’ translation manual that the native speaker’s ‘Gavagai’ might well be translated as ‘Lo, a rabbit’. On later occasions, some rabbited, some rabbitless, the linguist will volunteer ‘Gavagai?’ with the intention of eliciting the native speaker’s assent, dissent, or neither. In this way, the linguist can assess whatever inductive support there may be for their hypothesis that ‘Gavagai’ translates as ‘Lo, a rabbit’.

The distal stimulus, in this case a rabbit, serves as the criterion for the linguist’s inductive hypothesis that ‘Gavagai’ can be translated as ‘Lo, a rabbit’. However, what a sentence (even a one word sentence) and its translation share is the same meaning. In the case at hand, is the rabbit the meaning of ‘Gavagai’? No; that would be to confuse meaning with reference. What, then, is its meaning? Quine’s answer to this question (what he calls ‘stimulus meaning’) is given in terms of the proximal stimulus, namely, patterns of a subject’s activated nerve endings. Affording the native speaker a global pattern of non-verbal stimulation for a specific duration together with the linguist’s query ‘Gavagai?’ will elicit from the native speaker either assent, dissent, or neither. Patterns of stimulation which would prompt assent and patterns which would prompt dissent belong, respectively, to the affirmative stimulus meaning and negative stimulus meaning for that sentence and native speaker at that time. Stimulus meaning *simpliciter* is the ordered pair of the two. Patterns which would prompt neither assent nor dissent are irrelevant.

Given stimulus meaning, one might say that what ‘Gavagai’ and its translation ‘Lo, a rabbit’ share is the same stimulus meaning. However, this too would be wrong, for stimulus meaning (as just defined) is private: the native speaker’s nerves are distinct from the linguist’s nerves. It would be more accurate, but still problematic, to say that the native speaker’s stimulus meaning for ‘Gavagai’ and the linguist’s for ‘Lo, a rabbit’ are approximately the same. This is Quine’s approach in *Word and Object* (although he subsequently altered this account, as we shall see).

In the context of radical translation, it is stipulated that there are no bilinguals for the linguist to consult. So, the linguist must go about compiling the translation manual by observing the behaviour of native speakers, verbal and otherwise, and querying them with sentences for assent/dissent under various publicly observable circumstances. Thus, the criteria of translation remain keyed to distal stimuli, though the definition of stimulus meaning remains keyed to proximal stimuli. After all, one cannot plausibly expect the linguist to know anything about the native speakers’ or their own global patterns of activated nerve endings.

Given the behavioural limits of the empirical data of radical translation, Quine maintains in *Word and Object* that (1) observation sentences, like ‘Gavagai’, can be determinately translated; (2) truth functions (for example, ‘and’, ‘or’, ‘not’) can be determinately translated; (3) stimulus-analytic and stimulus-contradictory sentences can be identified, but not translated; and (4) questions regarding the intrasubjective stimulus synonymy of occasion sentences can be settled, if raised. (A stimulus-analytic sentence is one that a person would assent to after every stimulation: ‘There have been black dogs’, for example. A stimulus-contradictory sentence is one that a person would dissent from after every stimulation. The occasion sentences ‘Bachelor’ and ‘Unmarried man’ could count as intrasubjectively stimulus synonymous for a person, if they have the same stimulus meaning for him.)

However, if the linguist were to become bilingual (for example, if they forgot about translation and simply acquired ‘Jungle’ as a native speaker might, or nearly so), then according to Quine (1′) they could determinately translate all occasion sentences, not just observation sentences, and (4) above becomes superfluous. (Non-observational occasion sentences are those that require a new prompting stimulus each time they are queried, but lack the community-wide agreement characteristic of observation sentences, such as ‘There goes John’s old tutor’.) This leaves the linguist of *Word and Object* with determinate translations for (1′), (2) and (3).

However, in *Roots of Reference* (1974), Quine explains that the truth functions cannot be determinately translated

after all. One barrier concerns conjunction (‘and’): if each of a pair of sentences commands neither assent nor dissent, their conjunction can sometimes command dissent and sometimes neither dissent nor assent. If (to use Quine’s examples) ‘It’s a mouse’ and ‘It’s a chipmunk’ are neither affirmed nor denied, still their conjunction will be denied. Whereas if the components are ‘It’s a mouse’ and ‘It’s in the kitchen’ and neither is affirmed or denied, their conjunction will be neither affirmed nor denied. An analogous barrier stands in the way of determinately translating alternation (‘or’).

3 Indeterminacy of translation (cont.)

In discussing the translation of observation sentences and truth functions in Word and Object, Quine makes use of Neil Wilson’s principle of charity (see Wilson 1959). The central idea of the principle is that any proffered translation that construes the native speaker as holding some patently silly belief (for example, that the law of non-contradiction is false) is less likely than that the proffered translation is a bad one (see Charity, principle of §4). Thus, there is a sound methodological reason for translating a native speaker so as to construe them as holding true beliefs (true by the linguist’s own standards). However, Quine augments this principle with another: maximize psychological plausibility. This latter principle permits the linguist to translate a native speaker’s sentence by some patently false English sentence if, given the native speaker’s ‘outlandish’ rites and taboos or whatever, doing so is more plausible than translating the sentence in question by some true English sentence.

Putting the matter overly schematically, the next steps the linguist takes in constructing a manual of translation are as follows: (a) segmenting newly heard sentences uttered by native speakers into short recurrent parts (‘words’) which these sentences share with some of the observation sentences already translated; (b) segmenting further new sentences in ways that reflect the ‘words’ of the previous step, so that a lexicon and grammar begin to emerge; (c) generating new sentences in the native speaker’s language as recursion sets in; (d) continuing to fine tune the manual. Steps (a) to (d) make use of analytical hypotheses, hypotheses that go beyond the behavioural data: though analytical hypotheses should not contravene those data, neither are they supported by them.

In ‘Indeterminacy of translation again’ (1987), Quine articulates some constraints of a pragmatic nature which help to guide the linguist’s conjectures in this area, but clearly the linguist’s latitude for conjecture remains enormous. In fact, two linguists working independently of one another might well come up with equally successful ‘Jungle-to-English’ manuals which, despite being consistent with all the behavioural data, differ from one another in assigning to countless ‘Jungle’ sentences different English sentences as translations. Of these, countless different English sentences would not be interchangeable in English contexts. But which of these rival translation manuals is the correct one? There is no fact of the matter here; they are both correct. Such is the thesis of indeterminacy of translation.

Quine sums up the philosophical import of radical translation and of indeterminacy as follows:

> The point of my thought experiment in radical translations was philosophical: a critique of the uncritical notion of meanings and, therewith, of introspective semantics. I was concerned to expose its empirical limits. A sentence has a meaning, people thought, and another sentence is its translation if it has the same meaning. This, we see, will not do.
>
> (Quine 1987: 9)

The truth is more nearly the reverse: if some sentence is the translation of another, then it is proper to say that it has the same meaning. So, the idea of propositions as objectively valid translation relations, or as meanings of sentences, cannot be maintained. Furthermore:

> The critique of meaning leveled by my thesis of indeterminacy of translation is meant to clear away misconceptions, but the result is not nihilism. Translation remains, and is indispensable. Indeterminacy means not that there is no acceptable translation, but that there are many. A good manual of translation fits all checkpoints of verbal behavior, and what does not surface at any checkpoint can do no harm.
>
> (Quine 1987: 9)

So, the radical translator imposes about as much meaning as they discover.

Before surveying some criticisms of Quine’s indeterminacy thesis, we need to clear up an ancillary matter. In

Word and Object, Quine claims that the native speaker's stimulus meaning for 'Gavagai' and the linguist's stimulus meaning for 'Lo, a rabbit' are approximately the same. But Quine realized as early as 1960 that such intersubjective comparisons of stimulus meanings are problematic, for no two people's nerve nets are isomorphic. Consequently, in *Pursuit of Truth* (1990) Quine proposes to do without intersubjective comparisons of stimulus meaning. Empathy fills the gap. A rabbit scurries by; the native speaker utters 'Gavagai'. Empathizing with the native speaker, the linguist conjectures that were they in the native speaker's place they would have uttered 'Lo, a rabbit'. Thus, the linguist forms the tentative inductive hypothesis that 'Gavagai' translates as 'Lo, a rabbit'. Appealing to empathy instead of to approximate sameness of stimulus meaning forces Quine to reformulate his definition of 'observation sentence' (see Quine [1990] 1992: 43), but he does not drop the concept of stimulus meaning from his scientific semantics. Quine leaves to the neuropsychologists the task of accounting for the mechanisms underlying humans' ability to empathize.

4 Criticism

Indeterminacy of translation has been hotly debated by philosophers ever since the publication of *Word and Object*, and it is probably fair to say that more philosophers reject what they take to be the thesis than accept it. Some of the more widespread criticisms are: (a) Quine does not prove the thesis; (b) linguistics is underdetermined, but not indeterminate; (c) the thesis is unintelligible; and (d) the evidence for actual translation is not limited to that of radical translation. Let us briefly examine each of these criticisms in turn:

(a) *In 'Word and Object' Quine does not provide a deductive proof of his thesis of indeterminacy.* This is correct, but in addition to the more or less inductive argument presented there, Quine elsewhere offers two other arguments for indeterminacy. One of these, found in 'Epistemology naturalized' (1969a), takes Peirce's verificationism and Duhem's holism as premises supporting indeterminacy:

> If we recognize with Peirce that the meaning of a sentence turns purely on what would count as evidence for its truth, and if we recognize withDuhem that theoretical sentences have their evidence not as single sentences but only as larger blocks of theory, then the indeterminacy of translation of theoretical sentences is the natural conclusion.
>
> (Quine 1969a: 80-1)

A second argument is to be found in 'On the reasons for indeterminacy of translation' (Quine 1970: 179-81). There Quine argues for indeterminacy on the grounds of underdetermination of physical theory. He argues that translation of a foreign physicist's theory which is underdetermined by observable evidence will itself be underdetermined by translation of the theory's observation sentences. Thus, the translator will have to rely on analytical hypotheses, and different systems of analytical hypotheses can result in equally good, but incompatible, translations. Thus, the extent to which a physical theory is underdetermined by observation is a measure of the extent to which its translation is indeterminate. (But see Quine 1979: 66-7 for a reservation about this way of arguing for indeterminacy.)

(b) *It is true that scientific theory is underdetermined by all possible observations, and in so far as linguistic theory is a part of scientific theory it too is underdetermined, but there is no special indeterminacy that afflicts linguistics.* Quine responds to this criticism by pointing out that once one accepts some single physical theory from among its competitors as the whole truth about what there is, still, within that theory, indeterminacy of translation can occur. The reason is that all that matters to translation are the behavioural facts, and since behavioural facts do not fix translation, no further physical facts, not even the whole truth about nature, would do so.

(c) *The thesis of indeterminacy is unintelligible, for it repudiates meanings and at the same time claims that there can be rival manuals of translation assigning to some 'Jungle' sentence English sentences which diverge in meaning. But if there are no meanings, then how can English sentences diverge in meaning? And if they can diverge in meaning, then how can there be no meanings?* The response to this criticism is to explain how two English sentences can diverge in meaning without reifying meanings. Quine responds as follows:

> A manual of Jungle-to-English translation constitutes a recursive, or inductive, definition of a *translation relation* together with a claim that it correlates sentences compatibly with the behavior of all concerned. The thesis of indeterminacy of translation is that these claims on the part of two manuals might both be true and yet the two translation relations might not be usable in alternation, from sentence to sentence, without issuing in

> incoherent sequences. Or, to put it another way, the English sentences prescribed as translation of a given Jungle sentence by two rival manuals might not be interchangeable in English contexts.
>
> (Quine [1990] 1992: 48)

Once again, Quine's solution to the difficulty is along behaviourist lines.

(d) *There may well be indeterminacy of translation in the context of radical translation, but in the context of actual translation there is more evidence available to fix the meanings of sentences. For example, it is a fact of established usage, that is, verbal dispositions, that we translate the French sentence 'Il y a peut-être des êtres intelligents sur Mars' as the English sentence 'There may be intelligent beings on Mars'.* It is true that the context of radical translation was designed to expose the ultimate empirical data for translation, where the word 'ultimate' excludes verbal behaviour linked to systems of analytical hypotheses that over time have become customary. But the point remains, even for languages as close as French and English, that some uncustomary system of analytical hypotheses could produce different translation relations between French and English which are just as effective as the customary one. Indeed, as Quine points out, indeterminacy of translation begins with the translator's home language. English, for example, could be mapped into itself by using one 'Jungle-to-English' manual to translate English into 'Jungle', then using a rival 'Jungle-to-English' manual to translate 'Jungle' back into English.

The four criticisms dealt with above are by no means the only criticisms philosophers have levelled against Quine's thesis of indeterminacy of translation, but they are some of the more interesting and widespread ones.

5 Indeterminacy of reference

As we have seen, given the empirical data, the 'Jungle' observation sentence 'Gavagai' can be determinately translated by the English observation sentence 'Lo, a rabbit'. May we conclude from this that 'gavagai' is therefore a 'Jungle' term, and if so, that it can be determinately translated as 'rabbit'? According to Quine, the answer is 'no' on both counts. Termhood and reference are matters that can be settled only by appealing to analytical hypotheses. For example, assuming the linguist decides to construe 'gavagai' as a term, is it to be construed as an abstract singular term (for example 'rabbithood'), or as a concrete general term? If the latter, then 'undetached rabbit part' could serve just as well as 'rabbit' as a translation of 'gavagai'. After all, the same portions of space-time as are occupied by undetached rabbit parts are occupied by rabbits.

The only way to settle such questions is, according to Quine, by relying upon the 'Jungle' equivalents of English plural endings, pronouns, numerals, the 'is' of identity and its adaptations 'same' and 'other'. These constitute the cluster of interrelated grammatical particles and constructions with which the individuation of terms of divided reference in English is connected. Once a linguist has fixed these equivalences, they can put to the native speaker questions like 'Is this gavagai the same as that one?', 'Is this one gavagai or two?', and so on. Once the linguist is able to ask such questions, they can begin to determine whether to translate 'gavagai' as 'rabbit' or as 'undetached rabbit part'. However, before they can ask such questions, the linguist will have to formulate a system of analytical hypotheses in connection with some other 'Jungle' expressions, namely, those playing the role of that cluster of interrelated grammatical particles and constructions of English which govern reference. But that cluster is itself susceptible to indeterminacy of translation. Thus, if one overall system of analytical hypotheses works for translating some 'Jungle' expression into 'is the same as', perhaps some other workable but systematically different system would translate the same 'Jungle' expression as 'belongs with'. Therefore, when the linguist attempts to ask 'Is this gavagai the same as that?', they could unwittingly be asking 'Does this gavagai belong with that?'. So the native speaker's assent cannot be used to settle the reference of 'gavagai' absolutely. Consequently, even though this method of translation is the best the linguist can manage, it is not sufficient for settling absolutely the indeterminacy between translating 'gavagai' as 'rabbit' or as 'undetached rabbit part', and so on. The linguist can say only that 'gavagai' refers to rabbits relative to one manual, and to undetached rabbit parts relative to a rival manual. So long as these manuals are consistent with the behaviour of all concerned, there is no fact of the matter of what is 'really' referred to by 'gavagai'.

Quine has also argued for indeterminacy of reference independent of the indeterminacy of holophrastic translation. In what he calls his 'proxy function argument', Quine explains how:

> we might reinterpret every reference to a physical object arbitrarily as a reference rather to its cosmic complement, the rest of the physical universe. The old names and predicates would be introduced by ostension as usual, but it would be deferred ostension: pointing to what was not part of the intended object. Sensory associations would carry over similarly. The word ‘rabbit’ would now denote not each rabbit but the cosmic complement of each, and the predicate ‘furry’ would now denote not each furry thing but the cosmic complement of each. Saying that rabbits are furry would thus be reinterpreted as saying that complements-of-rabbits are complements-of-furry things, with ‘complements-of-rabbits’ and ‘complements-of-furry’ seen as atomic predicates. The two sentences are obviously equivalent.
>
> (Quine 1995: 71)

Quine goes on to explain that ‘cosmic complement of’ expresses what he calls a ‘proxy’ function: a one-to-one reinterpretation of objective reference. Such proxy functions leave the truth-values of the containing sentences undisturbed.

> It is a matter of reconstruing all terms and predicates as designating or denoting the proxies of what they had designated or denoted. A term that had designated an object *x* now designates the proxy of *x*, and a predicate that had denoted *x* now denotes the proxy of *x*. No big deal; we are proxying both sides of the predication, and it cancels out. We appreciated the triviality where the proxy was the cosmic complement.
>
> (Quine 1995: 72)

Thus, unlike the conjectural status Quine accords indeterminacy of translation of theoretical sentences as wholes, indeterminacy of reference has the apodictic certainty of a proof.

6 Criticism

As with indeterminacy of translation, indeterminacy of reference (or inscrutability of reference) has been vigorously criticized. The most widespread criticism is, perhaps, that Quine’s doctrine is inconsistent: it maintains that reference is and is not determinate. For example, it asserts that the native speaker’s ‘gavagai’ is indeterminate, since it can be adequately translated by ‘rabbithood’, by ‘undetached rabbit part’, by ‘rabbit’, and so on, while taking the reference of these English terms to be determinate. A full Quinian response to this criticism would take us far afield, but perhaps the following two quotations will suffice:

> To say that ‘gavagai’ denotes rabbits is to opt for a manual of translation in which ‘gavagai’ is translated as ‘rabbit’, instead of opting for any of the alternative manuals.
>
> And does the indeterminacy or relativity extend also somehow to the home language? In ‘Ontological relativity’ I said it did, for the home language can be translated into itself by permutations that depart materially from the mere identity transformation, as proxy functions bear out. But if we choose as our manual of translation the identity transformation, thus taking the home language at face value, the relativity is resolved. Reference is then explicated in disquotational paradigms analogous to Tarski’s truth paradigm…; thus ‘rabbit’ denotes rabbits, whatever *they* are, and ‘Boston’ designates Boston.
>
> (Quine [1990] 1992: 52; for his essay ‘Ontological relativity’, see Quine 1969b)

and:

> The very freedom vouchsafed us by the indeterminacy of reference allows us to *adopt* ostension as decisive for reference to observable concrete objects. We end up as we began, then, agreeing on the denotations of ‘rabbit’ after all: rabbits for all concerned. We may then merely differ on the deeper nature of rabbits: they are spatio temporal for some… sui generis for most. Adaptation of our usage must not, however, be allowed to obscure the lesson of proxy functions. Namely, a language-wide one-to-one reassignment of values to our variables has no effect on the truth of falsity of our statements.
>
> (Quine 1995: 75)

We turn, now, to a consideration of radical interpretation.

7 Radical interpretation

Mary utters ‘It’s raining’; Tom interprets her utterance to mean that it is raining. How is this possible? What could Tom know that would enable him to interpret the sentences of a natural language? Donald Davidson argues that we would have answers to these questions - a theory of meaning - if we had a theory meeting two requirements. First, the theory must provide an interpretation for a potential infinity of utterances of a speaker or group of speakers; second, the theory must be verifiable without assuming a detailed knowledge of the speaker’s propositional attitudes. The first requirement recognizes the holistic nature of linguistic understanding; the second requirement recognizes that the theory must not beg questions by assuming too much of what it is supposed to explain.

Davidson hypothesizes that a Tarski-like truth theory, suitably modified to apply to natural languages, just might meet these two conditions. To test his hypothesis, Davidson envisages a context of radical interpretation wherein an interpreter is faced with interpreting in one idiom talk in another. (For example, Kurt utters ‘Es regnet’ and Mary interprets his utterance to mean that it is raining.)

As Davidson points out in his essay ‘Radical interpretation’:

> The term ‘radical interpretation’ is meant to suggest strong kinship with Quine’s ‘radical translation’. Kinship is not identity, however, and ‘interpretation’ in place of ‘translation’ marks one of the differences: a greater emphasis on the explicitly semantical in the former.
>
> (Davidson 1984b: 126, n.1)

Or, as Quine has put the difference:

> Translation is not the field linguist’s goal. His goal is to command the native language and perhaps to teach it, whether for reasons of ethnography and philology or simply to implement fluent dialogue and successful negotiation with the natives. His undertaking, broader than translation, is *interpretation*. An untranslatable sentence, such as the one about neutrinos [‘Neutrinos lack mass.’] can still be interpreted, and that indeed is how we have learned it ourselves. For broadly semantic purposes, as Donald Davidson appreciates, interpretation is the thing. Translation is the narrower project, pertinent specifically to my concern over the fancied concepts of proposition and sameness of meaning.
>
> (Quine 1995: 80-1)

Thus, Quine’s radical translation and Davidson’s radical interpretation are devoted to different issues. Quine wants to discover the extent to which the empirical data determine meanings of sentences of a natural language; Davidson wants to discover what one could know that would enable one to understand the sentences of a natural language. Furthermore, the knowledge required for interpretation differs from the knowledge required for translation, for one could know that ‘Es regnet’ is translated as ‘Il pleut’ without knowing the interpretation (meaning) of either sentence. Davidson is fully aware of these differences, of course:

> The idea of a translation manual with appropriate empirical constraints as a device for studying problems in the philosophy of language is, of course, Quine’s. This idea inspired much of my thinking on the present subject, and my proposal is in important respects very close to Quine’s. Since Quine did not intend to answer the questions I have set, the claim that the method of translation is not adequate as a solution to the problem of radical interpretation is not a criticism of any doctrine of Quine’s.
>
> (Davidson 1984b: 129, n.3)

What, then, is the nature of the Tarski-like theory that Davidson believes might serve as a theory of meaning?

8 Truth theory

Alfred Tarski’s theory of truth is designed to apply only to artificial languages meeting certain formal requirements: extensional languages like first-order predicate logic with relations and identity. According to Davidson:

> What characterizes a theory of truth in Tarski’s style is that it entails, for every sentence *s* of the object language, a sentence of the form:
>
> *s* is true (in the object language) if and only if *p*.

> Instances of the form (which we shall call T-sentences) are obtained by replacing '*s*' by a canonical description of *s*, and '*p*' by a translation of *s*. The important undefined semantical notion in the theory is that of *satisfaction* which relates sentences, open or closed, to infinite sequences of objects, which may be taken to belong to the range of the variables of the object language. The axioms which are finite in number, are of two kinds: some give the conditions under which a sequence satisfies a complex sentence on the basis of the conditions of satisfaction of simpler sentences, others give the conditions under which the simplest (open) sentences are satisfied. Truth is defined for closed sentences in terms of the notion of satisfaction.
>
> (Davidson 1984b: 130-1)

Following Tarski's lead, Davidson's blueprint for a theory of meaning consists of axioms, rules and theorems. A finite set of axioms state satisfaction conditions for each of the object language's *semantical primitives* (basic terms and various other basic non-sentential expressions). An example might be: '*chien* applies to a thing if and only if it is a dog'. A finite set of rules allows proving T-sentences as theorems from the axioms. The resulting theorems are a potential infinity of T-sentences stating the truth-conditions for each object-language sentence. The proof of a T-sentence amounts to an analysis of how the truth or falsity of the object-language sentence depends on how it is composed from the semantical primitives. (These axioms, rules and T-sentences are, of course, stated in the language of the theory - the metalanguage.)

This general form of Davidson's theory of meaning reflects certain features of natural languages. First, since natural languages are learnable by finite beings, they must have a finite number of semantical primitives. Second, since natural languages consist of a potential infinity of sentences, the semantic features of such sentences must ultimately depend upon those of the semantical primitives. However, this does not imply that 'word' meaning is known somehow prior to sentence meaning. In fact, Davidson argues just the opposite: sentence meaning is known prior to word meaning. Words have whatever meanings they do as a result of their functioning in meaningful sentences. Third, like the axioms, the number of rules for proving T-sentences must be finite, and for the same reason. Finally, it is noteworthy that this Tarski-like theory of meaning has several obvious ontological advantages in that it makes no use of meanings as entities, nor of properties as denotatations of predicates, nor of states of affairs as denotatations of sentences.

Tarski's *Convention T* is that a theory of truth should entail T-sentences, in which descriptions of object-language sentences are linked to translations of those sentences in the metalanguage. For his own purposes, Davidson modifies Convention T in two fundamental ways. Tarski's Convention T relies on the notion of meaning (or translation) in order to explain truth. But meaning (or translation) is just the semantic notion that Davidson wants to explain, so he cannot, without begging questions, interpret Convention T in the manner of Tarski. Rather, Davidson construes Convention T as claiming that:

> an acceptable theory of truth must entail, for every sentence *s* of the object language, a sentence of the form: *s* is true if and only if *p*, where '*p*' is replaced by any sentence that is true if and only if *s* is.
>
> (Davidson 1984b: 134)

Thus, Davidson reverses Tarski's priorities: instead of assuming meaning in order to explain truth, he assumes truth in order to explain meaning.

Furthermore, since Davidson wants to apply the theory to natural languages (something which, as Davidson reports, Tarski explicitly denies can be done), he must allow for the fact that the object language contains a wide diversity of expressions, including proper names, functional expressions, indexicals, demonstratives, and so on. Admitting indexicals and demonstratives into the object language provides for the possibility of sentences which vary in truth-value according to time and speaker. Thus, Davidson's version of a Tarskian theory must take utterances of sentences, not sentences themselves, as truth vehicles. Davidson modifies Convention T accordingly:

s is true in *L* when spoken by *x* at *t* if and only if *p*.

Recall that Davidson believes we would have an answer to the question of what a person could know that would enable them to interpret the sentences of a natural language, if we had a theory meeting two requirements. First, the theory must provide an interpretation for a potential infinity of utterances of a speaker or group of speakers - a potential infinity of T-sentences. Davidson's modified version of Tarski's theory of truth is a blueprint for

constructing such a theory. Second, since that theory is to be an empirical theory about a speaker's (or speakers') behaviour, it must be verifiable - without assuming a detailed knowledge of the speaker's (or speakers') propositional attitudes. So, how is this second requirement to be met?

This is where the notion of a radical interpreter (like Quine's radical translator) serves as a useful heuristic. By imagining the routine of a radical interpreter at work, we come to appreciate that a theory of meaning is supported by verifying its T-sentences, and we come to see what ultimate evidence there is for verifying T-sentences.

9 Truth theory (cont.)

Imagine a radical interpreter who speaks only English, does not have access to bilinguals or dictionaries, and is attempting to interpret Kurt, who speaks only German. The interpreter has no prior detailed knowledge of the meanings of Kurt's utterances nor of Kurt's beliefs. Kurt utters 'Es regnet' at a time when it is raining near him. Judging that Kurt's utterance is both linguistic and intentional, the interpreter conjectures that Kurt holds 'Es regnet' to be true. The important methodological point to note, according to Davidson, is that the interpreter can spot such utterances purely on the basis of the speaker's observable behaviour, independently of knowing anything of the utterance's meaning or the speaker's beliefs. It is those utterances that a speaker (or speakers) hold true, at a time, under publicly observable circumstances, which constitute the ultimate evidence for T-sentences.

This ultimate evidence, about what sentences a speaker holds-true, is evidence not specifically about meaning, but about a combination of meaning and belief: a speaker believes whatever it is that they mean by the sentences. However, if the interpreter knew not only that Kurt holds a certain utterance true, but also what Kurt believes at the time, then the interpreter could extract the meaning of Kurt's utterance. Similarly, if the interpreter knew both that Kurt held a certain utterance true and its meaning, then they could extract Kurt's current belief. The problem is that there is no way to discover meaning which is independent of belief, and no way to discover belief which is independent of meaning. Thus, the central problem of interpretation is simultaneously to disentangle meaning and belief. How can a radical interpreter accomplish this task?

Suppose the interpreter, to use one of Davidson's examples (1984b: 135), can formulate the following T-sentence:

(T) 'Es regnet' is true-in-German when spoken by *x* at time *t* if and only if it is raining near *x* at *t*.

The interpreter's evidence for this T-sentence is:

(E) Kurt belongs to the German speech community and Kurt holds-true 'Es regnet' on Saturday at noon and it is raining near Kurt on Saturday at noon.

The interpreter's next step is to gather generalized evidence:

(GE) (*x*)(*t*) (if *x* belongs to the German speech community then (*x* holds-true 'Es regnet' at *t* if and only if it is raining near *x* at *t*)).

The interpreter can take (E) as evidence for (T) and for (GE), if they assume Kurt believes it is raining nearby at noon on Saturday, and if they assume that particular belief played a role in the causal chain prompting Kurt's utterance, 'Es regnet'. By using this procedure of holding belief constant as far as possible while solving for meaning, the interpreter can hope to solve the problem of the interdependence of belief and meaning.

But what justifies this procedure? After all, Kurt could be in error about it raining near him, and the interpreter could be in error about what distal stimulus is prompting Kurt's utterance and, hence, about the belief that is ascribed to Kurt.

'What justifies the procedure is the fact that disagreement and agreement alike are intelligible only against a background of massive agreement' (Davidson 1984b: 137). For example, if two people agree or disagree that what they see is a rabbit in tall grass, they must be in agreement regarding an indefinite number of other beliefs about rabbits, grass, distance, and so on. Furthermore:

> The methodological advice to interpret in a way that optimizes agreement should not be conceived as resting on a charitable assumption about human intelligence that might turn out to be false. If we cannot find a way to interpret the utterances and other behavior of a creature as revealing a set of beliefs largely consistent and true

> by our own standards, we have no reason to count that creature as rational, as having beliefs, or as saying anything.
>
> (Davidson 1984b: 137)

This mandatory principle of charity indicates that the verification of ascriptions of meaning and of belief are holistic in character. So while the principle of charity (namely, ‘optimize agreement’) does not guarantee that Kurt’s acceptance of ‘Es regnet’, or any other sentence considered in isolation, is to be deemed correct (in that it will be interpreted to mean something we accept), Davidson contends that the principle does guarantee that most of Kurt’s acceptances are in that sense correct.

> The method is rather one of getting a best fit. We want a theory that satisfies the formal constraints on a theory of truth, and that maximizes agreement, in the sense of making Kurt (and others) right, as far as we can tell, as often as possible.
>
> (Davidson 1984b: 136)

Unlike Quine, who advocates the principle of charity at the level of translating ‘Jungle’ observation sentences like ‘Gavagai’ and the ‘Jungle’ equivalents of truth functions like ‘and’, ‘or’ and ‘not’, Davidson advocates the principle at every level of interpretation (see Davidson 1984b: 136, n.16). However, his principle of charity definitely involves more than the basic methodological precept ‘optimize agreement’:

> It is impossible to simplify the considerations that are relevant [for dealing with disagreements], for everything we know or believe about the way evidence supports belief can be put to work in deciding where the theory can best allow error, and what errors are least destructive of understanding. The methodology of interpretation is, in this respect, nothing but epistemology seen in the mirror of meaning.
>
> (Davidson 1984c: 169)

It is Davidson’s contention that for a theory that satisfies the formal constraints on a theory of truth, and which optimally fits the evidence about utterances held true, each of its T-sentences will yield an acceptable interpretation. Moreover, Davidson believes - and for Quinian reasons - that if there is one such theory for some object language, then there are many. Thus, Davidson’s theory of meaning possesses its own forms of indeterminacy and inscrutability.

10 Criticism

Davidson’s theory of radical interpretation has precipitated a tremendous amount of discussion of the topic among philosophers. Two of the more general criticisms of Davidson’s programme are: (a) the construction of a Tarski-like theory of meaning for an entire natural language is implausible; and (b) Davidson’s rendering of Convention T is too weak to yield interpretations.

(a) *The construction of a Tarski-like theory of meaning for an entire natural language is seen to be implausible when one considers the number and variety of idioms whose truth-conditions are not fully understood; idioms like ‘knows that’ and ‘believes that’, contrary to fact conditionals, and so on.* Citing some of his own work on attributions of attitudes and performatives, as well as other philosophers’ work on proper names, mass terms, ‘ought’, and so on, Davidson remains optimistic that many of these problems will be solved in ways consistent with his Tarski-like theory of meaning (see Davidson 1984b: 132-3).

(b) *Davidson’s rendering of Convention T is too weak to yield interpretations.* Recall, for Davidson, Convention T says that *s* is true if and only if *p*, where ‘*p*’ is replaced by any sentence that is true if and only if *s* is. Hence, we get the following T-sentence:

(1) ‘John is a renate’ is true if and only if John is a renate.

But, since all renates are cordates, and vice versa, we also get the following T-sentence:

(2) ‘John is a renate’ is true if and only if John is a cordate.

But even if (1) is an interpretation of the object-language sentence ‘John is a renate’, surely (2) is not. So Convention T is too weak.

Davidson's response to this problem is two-fold: he emphasizes that T-sentences are verified not individually but holistically, and he recognizes that T-sentences (and axioms) must be viewed as empirical laws. In accord with the latter point, T-sentences which yield interpretations must not only be true, they must also be capable of supporting counterfactual claims. Presumably (1) supports the counterfactual:

(1′) If 'John is a renate' were false, then John would not be a renate.

But (2) does not support the counterfactual:

(2′) If 'John is a renate' were false, then John would not be a cordate.

Davidson would explain this difference, presumably, by claiming that (1) does, but (2) does not depend ultimately on certain causal relations between speakers and the world (see Davidson 1984a: xiv).

These criticisms of Davidson's programme are by no means the only ones; many questions have been raised about his handling of indexicals, ambiguity, word-meaning versus sentence-meaning, the principle of charity, and so on.

Rahner, Karl (1904-84)

Rahner sought to offer an account of the Christian faith that would be credible to the modern mind. His early philosophical works lay the foundation for this theological project. Using both the method and categories of the early Heidegger, Rahner placed the thought of the medieval philosopher and theologian Thomas Aquinas in conversation with modern philosophy. He asked of Aquinas' epistemology Kant's question about the conditions of human subjectivity which make knowledge possible. Rahner argued that Aquinas' description of knowledge and human freedom requires, as its necessary condition, that the subject possess an openness to a universal horizon of being, an openness to God. There is, in the structure of subjectivity, a constitutive, experiential, a priori relationship with the divine mystery. While this openness occurs within an individual's self-awareness, it is always mediated by and interpreted through the objects, people, language and ideas that make up one's historical context (the categorical). In his theology, Rahner argued that the true nature of humanity's relationship with God had been revealed by Jesus to be one of absolute nearness. Rahner rendered Christian doctrines credible by correlating them with the transcendental experience of a God who is near.

1 Life

Karl Rahner was born near Freiburg, Germany, on 5 March 1904. He entered the Society of Jesus in April 1922 and, as a Jesuit seminarian, studied the Thomistic philosophy which then dominated Roman Catholic thought. In personal study he read the works of the Belgian Jesuit Joseph Maréchal.

In 1934, two years after ordination to the priesthood, Rahner was sent to Freiburg University to take a doctorate in philosophy. While he pursued his degree under the Thomist Martin Honecker, Rahner attended Martin Heidegger's lectures and seminars. He wrote a dissertation on Aquinas' epistemology which Honecker rejected because Rahner's interpretation of Aquinas was too much influenced by Heidegger. The dissertation was published in 1939 as *Geist in Welt* (*Spirit in the World* (1968)). Its perspective is the philosophical ground for Rahner's later theology. Rahner left Freiburg in 1936. In 1937, he satisfied the doctoral and post-doctoral requirements in theology at the University of Innsbruck and lectured there until the theology faculty was abolished by the Nazis in July 1938. He spent the war years at the Pastoral Institute in Vienna and later as a pastor in Bavaria. His philosophy of religion, *Hearers of the Word*, appeared in 1941.

After the Second World War, Rahner returned to teach theology at Innsbruck. He became one of the most influential and prolific Roman Catholic theologians. During the Second Vatican Council, he served as theological advisor to Cardinal König of Vienna. He also held positions at the Universities of Munich (1963-7) and Münster (1967-71). Most of Rahner's theological publications appear as essays collected in the sixteen volumes of *Schriften zur Theologie* (1954-84) (*Theological Investigations* (1961-92)). His *Grundkurs des Glaubens* (1976) (*Foundations of Christian Faith* (1978)) offers a systematic though incomplete presentation of his thought. Rahner also edited and contributed to theological dictionaries and published a number of significant works in spiritual theology. After retiring in 1971, he continued to lecture and write until his death on 30 March 1984.

2 Context and project

Rahner is primarily a Roman Catholic theologian. The aim and content of his thought emerge from the context of the Church's intellectual life in the mid-twentieth century. In 1879, Pope Leo XIII published the encyclical *Aeterni Patris*, which granted the thought of Thomas Aquinas a privileged status within the Catholic Church. Against the scepticism of modern thought, the philosophy of Aquinas represents a realism which both offers rational proof of God's existence and establishes the divine attributes necessary to ground historical revelation. In this way it illuminates Christian revelation and serves Catholic theology (see Thomism).

Leo XIII's encyclical led to a revival of Thomistic thought within the Church. By the middle of the twentieth century, this revival had produced an unanticipated pluralism in interpretations of Aquinas. Some saw Aquinas as an alternative to the errors of modern philosophy. Others, such as the Jesuits Pierre Rousselot and Joseph Maréchal, interpreted Aquinas in the light of modern questions and insights. In *Le point de départ de la métaphysique (The Starting Point of Metaphysics)* Maréchal began a dialogue between the epistemologies of Kant and Aquinas. By Rahner's own account, the basic and decisive philosophical direction of his thought came from

Maréchal.

The Neo-Kantianism that dominated German university philosophy at the beginning of the twentieth century assumed the correctness of Kant's critique of metaphysics. In his *Critique of Pure Reason* (1781), Kant argued that human knowledge is properly directed towards the objects of sensation. Efforts to know transcendent realities such as being, human freedom and God, while inevitable, are futile. The human capacity for knowledge is properly employed only when directed towards the physical world presented in sensation. Metaphysics and natural theology do not fall within reason's competence (see Kant §§4-8).

Pursuing Maréchal's project and influenced by Heidegger's efforts to retrieve the question of being, Rahner sought a Thomistic response to Kant's critique of metaphysics. Rather than eschewing modernity's turn to the subject as the abandonment of realism, Rahner offers a transcendental interpretation of Aquinas which leads to an epistemology, an ontology, and an argument for the existence of God. His thought not only offers a Thomistic response to modern philosophical questions, it also serves as the foundation for his theology. The notion of God which Rahner draws from Aquinas serves as an experiential reference in his existential interpretation of Catholic doctrine. In sum, Rahner's thought retrieves a Thomistic ontology within the context of modern thought and, in doing so, grounds a credible account of Christian faith.

3 Fundamental ontology

Rahner observes that Aquinas, like Kant, roots all knowledge in sensation. The proper object of human knowing is the physical world perceived by the senses. Rahner's rejected doctoral dissertation *Spirit in the World* is an interpretation of *Summa theologiae* Ia, question 84, article 7, in which Aquinas asserts that there is nothing in the human intellect apart from what is attained by turning to phantasms (that is, to objects sensed and imagined). Rahner's interpretation of Aquinas is not a literal rendering of Aquinas' historical position. Rather Rahner adopts Heidegger's interpretive method of retrieval. He uncovers possibilities in Aquinas' thought (in response to Kant) which could not have occurred to a medieval thinker. If human knowledge is properly directed towards objects of sensation, as Kant and Aquinas hold, how are metaphysics and natural theology possible?

Knowledge is more than sensation (after all, animals sense the same things as humans). Knowing is the work of what Aquinas calls the agent or active intellect. Attending to sense data, one forms a concept or idea, such as the concept of 'dog'. But having concepts is not yet knowing. Ideas are the means by which the human intellect comes to the intelligibility of sensed objects. One attains truth (that is, what is) in the act of judgment that, for example, this concrete object is a dog. Thus for Aquinas, knowledge consists of sensation, conceptualization (abstraction) and judgment (see Aquinas, T. §11).

Rahner then asks of this account of knowledge Kant's transcendental question. What are the conditions that make knowing possible? What must be true of the human intellect for it to move from sensation through conceptualization to judgment? Rahner thereby follows Kant's transcendental approach and attends to the a priori conditions of subjectivity for knowing. He is a transcendental Thomist in that he asks Kant's question of Aquinas' description of knowledge.

Using a term from Heidegger, he contends that the intellect must possess a *Vorgriff*, a pre-grasp of universal being as the necessary condition for the activities of forming universal concepts and judging. The *Vorgriff* is crucial to Rahner's metaphysics and philosophy of religion. For the intellect to form universal concepts from the particular objects of sensation it must have an a priori openness to universality. Again, for the intellect to judge that this object is a dog and nothing else requires a pre-grasp of the nothing else, of a universal horizon of all other beings. The *Vorgriff* of universality is not itself a concept or an object of direct experience. It is a dynamism towards all being, manifest and experienced in the activity of the intellect as the necessary condition for that activity.

What is this universality? In judgment, one asserts what a thing is against an infinite horizon of what it is not. Judgment requires, as its necessary condition, an anticipation of the absolute range of all knowable objects. The range of the intellect is unlimited. It is ordered towards knowing everything that is, all being. If judgment attains what is (being), the absolute range of universality must be absolute being. Absolute being is what a Thomist means by God.

Furthermore, in judgment one asserts what a thing is. One attains the intelligibility of an object (for example, 'that

is a dog'). Being, what is, and intelligibility coincide. Being and knowledge must constitute an original unity. Thus absolute being is pure intelligibility, a knower knowing itself, subject and object, absolute and pure self-presence. Pure being is a pure luminosity in which knower and known are identical. There is a hierarchy of being which is a hierarchy of self-possession, of intelligibility, of knowledge. God is one simple act of self-knowledge in which God knows all that is, all being. Humans, lower in the hierarchy, come to self-possession by knowing particular beings. Every act of knowledge involves an encounter with the other in sensation, in-the-world, and the return to self in judgment ('This is a dog and not I'). One possesses the known in the return to self. Human truth is an increase in being, in that the knower possesses more of what is. Knowledge is an existential occurrence in which the knower becomes.

4 Freedom

Human nature is not static. Rahner adopts the early Heidegger's notion of human existence as freedom-in-the-world. To be human is to be handed over to oneself to become. The capacity to make specific choices is rooted in this primordial being as becoming. Human freedom is finite in that persons become through their commerce with other people and objects in-the-world, and through the possibilities offered by a particular time and place. But the performance of freedom requires, as its necessary condition, the *Vorgriff* of unlimited being. Human freedom is unavoidable transcendence, a becoming without limit. To set limits to human becoming - to assert, for example, that human beings are creatures of their environment and no more - is already to transcend those limits. To know oneself is already to transcend, to stand beyond self. Like knowing, the performance of human freedom requires as its necessary condition the subject's openness to an unlimited horizon of being. Human freedom is exercised within the ever mysterious horizon of infinite being. One determines one's being before absolute mystery.

Thus Rahner argues that an experiential openness to absolute being (God) is the necessary condition for human knowledge and freedom. But God remains a mystery. In *Hearers of the Word*, Rahner states that the divine may be merely the mysterious horizon within which human transcendence occurs. It is also possible, though, for God to establish and reveal a more intimate relationship with human creatures.

5 Theology

Rahner's fundamental ontology is the enduring context for the theology which constitutes the bulk of his work. He distinguishes two poles of human experience - object and subject, the categorical and the transcendental. The things, events, possibilities and people one encounters are the categorical. All these encounters happen to a transcendental subject. The *Vorgriff* occurs in the transcendental. Locating the experiential reference for God in the transcendental determines the direction of Rahner's theology.

Speech about God, religious and philosophical, employs categories from historical contexts (for example, horizon, depth, father, creator) to point towards and interpret humanity's transcendental relationship with the divine. Rahner concludes his philosophy of religion described in *Hearers of the Word* with the suggestion that we search history to see if God has, in fact, revealed the character of humanity's constitutive relationship with the divine mystery.

The core truth of the Christian faith is that in Jesus, God has revealed the nature of humanity's relationship with the divine to be one of absolute nearness. God is offering God's very self to each human person for eternal communion. Borrowing a Heideggerian term, Rahner asserts that God's self-offer is an existential, constitutive element of human existence. The transcendental experience is revealed to be an experience of this offer. Human freedom is the capacity to determine who one is before God, to affirm or negate the divine self-offer. Specific Christian teachings give expression to this one core truth and its implications. This truth is proclaimed by the Church within history and can be grasped by all people because it calls them to what they already are.

An example can clarify how Rahner's theology works. Belief in the resurrection of Jesus is the foundation of Christian faith. Yet many find it difficult to believe because they think of Jesus' resurrection as a categorical event, the resuscitation of a dead body within history. Setting aside historical and categorical questions about what happened to Jesus after his death, Rahner suggests that the meaning of Jesus' resurrection is attained by correlating this doctrine with the transcendental experience of God's nearness. Again following Heidegger, Rahner describes

human existence as freedom-toward-death. Human beings know they will die, and in the anticipation of death the question inevitably occurs as to whether how one lives, who one becomes in freedom, makes any difference. Does human existence have any meaning or are we simply freedom becoming towards nothing? Since we are helpless to maintain ourselves in existence at death, the question of meaning raises the possibility that what we have achieved in freedom might be granted some final, enduring validity. This possibility of meaning, which Rahner calls transcendental hope, necessarily occurs to everyone. Even the assertion that life is meaningless implies a grasp of what meaningful existence might be. This hope is the experiential manifestation of God's self-gift to every human being. Hope occurs because humanity exercises its freedom within the horizon of God's self-offer.

Transcendental hope is the horizon for hearing and believing the proclamation that Jesus is risen. God has granted final, enduring validity to Jesus' life. From this side of the grave, understanding of the resurrection is rooted in freedom's option that life is meaningful. This option occurs in a life of generosity and service. Hope is rejected in selfishness. Freedom's 'yes' to the divine self-offer may or may not take the form of explicitly religious and Christian categories. But any individual who opts for meaning implicitly affirms the truth of Jesus' resurrection and Christian revelation.

Ramakrishna Movement

Although the Ramakrishna Movement was born in Bengal and influenced by Christian missionary activity and Western Orientalism, its understanding of Hinduism has become the standard for modern educated Indians. Drawing on the spiritual inspiration of its guru, Sri Ramakrishna (1836-86), and the dynamic preaching of his main disciple, Swami Vivekananda (1863-1902), the Ramakrishna Order has founded centres throughout India and the West. Calling his system 'Practical Vedānta', Vivekananda laid claim to the classical Advaita Vedānta associated with Śaōkara. Unlike Śaōkara, though, Vivekananda elevated selfless social work to a spiritual path equal in value to meditation, devotion and gnosis. The swamis of the order combine traditional Hindu religious practice with the administration of educational and medical institutions on the model of Christian missions. Vivekananda's vision of Indian culture as united and renewed by his humanistic Hinduism has inspired other gurus as well as Hindu nationalists.

1 Background

The Ramakrishna Movement, a highly successful Hindu religious and missionary order, was first propagated by Swami Vivekananda (1863-1902), a disciple of Sri Ramakrishna (1836-86), in the 1890s. Vivekananda received training in Western philosophy at a college of the Scottish Free Church in Calcutta, capital of the British Raj. Before joining Sri Ramakrishna during his college years, Vivekananda belonged to the Brahmo Samaj, the first major Hindu reform movement (see Brahmo Samaj). Wounded by the scathing attacks on Hindu tradition by Christian missionaries, by the triumphalist histories of Anglocentric Orientalists, and by discriminatory policies in the colonial civil service and the courts, members of the emerging Bengali Western-educated middle class took refuge in literature, the arts and religion. A few, like Vivekananda, sought to represent their culture in a way that would integrate their conflict-torn identities within and, at the same time, stand up to Western scrutiny. By the time of Lord Curzon's partition of Bengal in 1905, a mark of Vivekananda's success was that his new Hinduism was feeding the resistance movement against British colonialism.

Those educated Bengalis who did not completely forsake their cultural tradition took heart from a long line of sympathetic Orientalists - from Sir William Jones in the late eighteenth century to Max Müller in the late nineteenth. Both the Brahmo Samaj and Vivekananda's Ramakrishna Movement felt empowered by such work to imagine a reconciliation of the conflict, as they saw it, between East and West. Both Keshub Chunder Sen, leader of the Brahmo Samaj, and Swami Vivekananda took inspiration also from Sri Ramakrishna, who seemed to offer a liberal outreach from the authentic depths of the indigenous tradition (see Brahmo Samaj §2). Keshub preached a New Dispensation based on a personal mixture of Indian and Western traditions; Vivekananda convinced his contemporaries that his synthesis was fully rooted in Hinduism, that he 'spoke nothing but the Upaniṣads'. Vivekananda followed Orientalists in presenting the classic Hindu systems in Western terms. His ultimate intention, however, was to universalize key Vedāntic concepts such as Brahman, *ātman* and *mokṣa* into a controlling framework of norms and values for the entire world.

Vivekananda assumed that each culture represents a unique national spirit which complemented that of other nations. Here Vivekananda combined European romanticism with the caste theory of *jātidharma* - the notion that each class of persons has an inherent and unique role in society. Vivekananda tried to divine this intercultural cosmology by weighing the strengths and weaknesses of each nation's religion and society:

> Which is better, the social freedom of America, or the social system of India with all its restrictions? The American method is individualistic. It gives an opportunity to the lowest. There can be no growth except in freedom, but it also has obvious dangers. Still, the individual gets experience even through mistakes. Our Indian system is based entirely upon the good of the *samāj* [society]. The individual must fit into the system at any cost. There is no freedom for the individual unless he renounces society and becomes a *sannyāsin* (monk). This system has produced towering individuals, spiritual giants. Has it been at the expense of those less spiritual than themselves? Which is better for the race? Which? The freedom of America gives opportunities to masses of people. It makes for breadth, whilst the intensity of India means depth. How to keep both, that is the problem.

(Eastern and Western Admirers 1964: 218-9)

This dialectic was typical of Vivekananda's thought process. Romantic Orientalism assumed that the great cosmic struggle of the time pitted a materialist West against a spiritually gifted but weakened East. Vivekananda assimilated these two entities to the primary *guṇas* (qualities) of Sāōkhya cosmology: *rajas* (passion, power) and *tamas* (inertia) respectively. When *rajas* and *tamas* regain balance with each other, the universe attains to *sattva* (a salvific equilibrium) (see Sāōkhya §2). Through a cultural exchange of qualities, the East would regain its vitality and teach the West its spiritual insights.

2 Principal tenets

Although Ramakrishna introduced Vivekananda to Advaita Vedānta, Vivekananda's readings in Herbert Spencer, Ernst Haeckel and Paul Deussen confirmed the viability of metaphysical nondualism as a framework for cross-cultural apologetics and assimilation. Knowledge of the Absolute equalized all competing doctrines and symbols by uniformly nullifying them, but the penultimate perception of One-and-Many equally exalted them:

> All we know about things now or may know in future are but relative truths. It is impossible for our limited mind to grasp the absolute truth. Hence, though truth be absolute, it appears variously to diverse minds and intellects. All these facets or modes of truth belong to the same class as truth itself, they being based on the same absolute truth. This is like the different photographs of the same sun taken from various distances. Each of them seems to represent a different sun. The diverse relative truths have the same kind of relation with the absolute truth. Each religion is thus true, just because it is a mode of presentation of the absolute religion.
>
> (Eastern and Western Admirers 1964: 28)

Vivekananda wanted especially to include the materialist viewpoint - 'The materialist is right! There is but One. Only he calls that One Matter, and I call it God!' (Nivedita 1910: 23). Vivekananda wanted to claim like Herbert Spencer that he had reconciled religion and science. But the styling of philosophical differences as mere terminological distinctions recalls Ramakrishna's simple dictum that the different gods of the various religions are like the different names for water in various languages.

Following the Orientalist Sir William Hunter, Vivekananda linked Vedānta cosmology with Western evolutionism. For him evolution was a soteriological process:

> From the lowest form of life to man, the soul is manifesting itself through nature. The highest manifestation of the soul is involved in the lowest form of manifest life and is working itself outward through the process called evolution. The whole process of evolution is the soul's struggle to maintain itself.
>
> (Vivekananda 1977 vol. 6: 35-6)

Vivekananda maintained that the Indian theory taught that the process did not occur through competition (Spencer's survival of the fittest) but by the 'infilling of nature' (*prakṛtyāpūrāt*). Among humans, evolution took place not by overcoming obstacles but by letting the obstacles 'give way' through 'education and culture'. This theory is more 'consonant with reason' and less 'evil'. Darwin's theory applied to plants and animals; human culture advanced not by means of human competition and cooperation with Natural Law, as Spencer argued, but rather on the basis of a struggle against Nature, as Thomas Huxley argued, and self-sacrifice for the good of society.

Vivekananda used evolutionism also to frame his philosophy of history. He endorsed the views of Spencer and Müller that religions and nations evolve and progress in history, though not without cyclical periods of decay or regression. In the case of India, he postulated a Golden Age followed by degeneration, and he looked forward to a national renewal. Vivekananda was not promoting historical determinism, however. In March 1899 he said to his main Western disciple, Sister Nivedita (the Irishwoman and Indian nationalist Margaret Noble):

> I say, Margot, I have been thinking for days about [Spencer's] line of least resistance; it is a base fallacy. It is a comparative thing.… The history of the world is the history of a few earnest men, and when one man is earnest the world must just come to his feet. I am not going to water down my ideals, I am going to dictate terms.
>
> (Eastern and Western Admirers 1964: 278)

Thomas Carlyle's Great Man theory, another favourite of Vivekananda's, here overcame Spencer's Natural Law.

Vivekananda also questioned Western progressivism from a more traditional Indian view. Ramakrishna taught that ‘The world is like a dog’s curly tail… people have been striving to straighten it out for years… when they let it go, it has curled up again’ (Vivekananda 1977 vol. 1: 79). Vivekananda preached that people should aspire to progress, to do some good for society, but with the goal in mind of spiritual progress rather than worldly perfection: ‘You cannot overcome the idea of progress. But things do not grow better. They remain as they were, and we grow better, by the changes we make in them’ (Nivedita 1910: 148).

The goal of religion in classic Advaita Vedānta was *mokṣa*, a state in which the self frees itself from consciousness of both self and world. Ramakrishna privileged the state of exalted devotion in which one retains consciousness of one’s self in order to play in the consciousness of God. Vivekananda combined Advaita Vedānta and Western humanism to preach that because every *ātman* was truly Brahman, service to humanity was service to God.

Rāmānuja (d. *circa* 1137)

A south Indian Brahman, Rāmānuja was the theistic exegete of the Vedānta who propounded a doctrine which came to be known as viśiṣṭādvaita *or 'qualified monism'. As such, he is often said to be the founder of the most prominent of the four schools of the Vaishnava religion, the Śrīsampradāya, although in fact he considered himself to be a participant in an already ancient tradition. Rāmānuja's version of Vedānta challenges the uncompromising nondualism of Śaṇkara.*

1 Life and works

Nine works are ascribed to Rāmānuja by his biographers: three are commentaries on the *Vedāntasūtra* of which the extensive *Śrībhāṣya* is the most important; *Vedāntasāra* (The Essence of Vedānta) and *Vedāntadīpa* (Light on the Vedānta) are shorter commentaries on the same text. His other philosophical works are a commentary on the *Bhagavad Gītā* and an independent summary of his doctrine, *Vedārthasaṃgraha* (A Compendium of the Meaning of *the Veda*) (*c*.1016-*c*.1137). *Nityagrantha* (A manual of Daily Worship), as well as three shorter devotional works are also ascribed to Rāmānuja. Of these nine, only *Śrībhāṣya*, *Bhagavad Gītābhāṣya* and *Vedārthasaṃgraha* are accepted without dispute to be his own. Of the remaining six, scholarly consensus leans towards accepting the two shorter commentaries on Vedānta as genuine and the others as later ascriptions.

Rāmānuja first took instruction in the Vedānta aphorisms from Yādavaprakāśa, who himself had composed a commentary on them in the *bhedābheda* ((simultaneous) difference and identity) tradition. Following Bhāskara (*c*.900), Yādavaprakāśa gave equal ontological status to both Brahman, the ultimate reality, and the phenomenal universe. However, in Rāmānuja's opinion, his teacher was inclined towards a monistic interpretation as he considered īśvara, the personal god, to be part of the phenomenal universe and not identical with Brahman. After his break with Yādavaprakāśa, Rāmānuja transferred his loyalties to Yāmunācārya, the head priest of the Viṣṇu temple at Śrīraōgam and representative of the devotional creed of the Āḻvārs. Although he had no personal contact with Yāmuna, legend has it that Rāmānuja was given a posthumous order to undertake several tasks, including that of presenting a systematic commentary on the Vedānta which was in opposition to that of Śaōkara, through which commentary a philosophical basis would be given to the devotional religion presented in the hymns of the Āḻvārs. This Rāmānuja was able to do through combining a realistic metaphysic with a theology of revelation.

2 Epistemology

Like Śaōkara, Rāmānuja accepted three sources of knowledge: direct perception, inference and revelation (See Knowledge, Indian views of). Although immediate experience of Brahman is the ultimate proof of its truth, revelation is the only dependable source of knowledge for the aspiring seeker, direct perception being subject to various sensory defects and inference to other human failings (see Brahman). Among the sources of revelation, Rāmānuja follows Śaōkara in giving precedence to the Upaniṣads, the *Brahmasūtras* and the *Bhagavad Gītā*, as the measure of all revelatory sources. In addition, he made extensive use of the Purāṇas, primarily the *Viṣṇupurāṇa* (*c*. fourth century AD).

3 Theology

According to Śaōkara, Brahman, the supreme truth, is pure existence with no qualities; it is consciousness alone without differentiation of subject and object (see Śaōkara). Rāmānuja understood that an eternal distinction between the individual soul and Brahman is essential to monotheistic religion. The religious relationship between God and the individual which Śaōkara considered to be conventional, that is, merely an aspect of the phenomenal existence, had to be shown to be ultimate. Rāmānuja thus rejected Śaōkara's theory of two levels of revelation, claiming that all revealed statements should be given equal status. Just as certain Upaniṣadic passages illustrating the ultimacy of the monotheistic position presented a problem to Śaōkara, Rāmānuja had to accept and deal with others which showed that the individual souls and the supreme truth were not different. This he did by showing that the distinctions between the selves, the phenomenal world of matter and God were maintained even while they formed a unity. Thus, the nondual (*advaita*) ultimate reality was shown to be qualified (*viśiṣṭa*) by the existence of the finite conscious living beings and the unconscious universe. All objects of experience are characterized by generic and specific properties. Therefore, Śaōkara's characterization of Brahma as pure existence which has no

properties was seen as a figment of the imagination. Yāmunācārya had argued persuasively for the existence of the soul by showing that despite the changes in the objects of knowledge, the knower remains essentially the same. Individual consciousness remains constant and unchanging despite the changes in the body. This is further confirmed by the sense of difference between the self and the body, as evidenced by a statement such as 'this is my body'. Rāmānuja expands on this idea with his doctrine of inseparability through which he argues that no soul can be without a body, for there is no such thing as consciousness without a field of consciousness, that is, a body. Similarly, God or Brahman cannot be pure consciousness (as is held by Śaōkara), because such a thing lies outside the realm of experience. Since nothing exists outside of Brahman, that of which he is conscious is also himself. The object of God's consciousness, that is, the creation consisting of both unconscious matter and individual souls, is thus considered, by analogy with the individual consciousness, to be his body. Despite the changes in the universe, his body, he, as the soul of the universe, remains unchanged and unchanging. Through this reasoning, the universe is given the same ontological status as the ever-constant eternal ground of being, because the one is dependent on the other. Just as changes in the body of the individual do not accrue to that individual, similarly the various transformations of the universe do not constitute a change in the essence of Brahman.

4 Soteriology

The individual soul has been confounded through his association with unconscious matter and so identifies with his material body. Through surrender and devotion he can attain a body which is suitable for directly experiencing and eternally serving the personal God. This is the ultimate goal of life. After Rāmānuja's death, his followers split over whether surrender, with its implication of complete dependence on the grace of God, or devotion, interpreted as a type of doctrine of works, was the more important aspect in the path of attaining God.

Ramsey, Frank Plumpton (1903-30)

Before Ramsey died at the age of 26 he did an extraordinary amount of pioneering work, in economics and mathematics as well as in logic and philosophy. His major contributions to the latter are as follows. (1) He produced the definitive version of Bertrand Russell's attempted reduction of mathematics to logic. (2) He produced the first quantitative theory of how we make decisions, for example about going to the station to catch a train. His theory shows how such decisions depend on the strengths of our beliefs (that the train will run) and desires (to catch it), and uses this dependence to define general measures of belief and desire. This theory also underpins his claim that what makes induction reasonable is its being a reliable way of forming true beliefs, and it underpins his equation of knowledge generally with reliably formed true beliefs. (3) He used the equivalence between believing a proposition and believing that it is true to define truth in terms of beliefs. These in turn he proposed to define by how they affect our actions and whether those actions fulfil our desires. (4) He produced two theories of laws of nature. On the first of these, laws are the generalizations that would be axioms and theorems in the simplest true theory of everything. On the second, they are generalizations that lack exceptions and would if known be used to support predictions ('I'll starve if I don't eat') and hence decisions ('I'll eat'). (5) He showed how established, for example optical, phenomena can be explained by theories using previously unknown terms, like 'photon', which they introduce. (6) He showed why no grammatical distinction between subjects like 'Socrates' and predicates like 'is wise' entails any intrinsic difference between particulars and universals.

1 Mathematics

The British philosopher Frank Plumpton Ramsey graduated in mathematics from Trinity College Cambridge in 1923, became a Fellow of King's College in 1924 and a University Lecturer in Mathematics in 1926. In his short life he did work in mathematics and economics which created new branches of those subjects. But his vocation and greatest achievements were in philosophy, influenced by and influencing his Cambridge colleagues, especially Russell, Wittgenstein and Keynes. His first major work, on 'The Foundations of Mathematics' (1925) (this can be found, as can all his other works cited in this entry, in Ramsey (1990a)), makes two key improvements to the attempted reduction of mathematics to logic in Whitehead and Russell's *Principia Mathematica* (see Logicism). First, Ramsey tightens *Principia*'s definition of mathematical propositions as purely general by requiring them also to be tautologies in the sense of Wittgenstein's *Tractatus*. Second, he shows that it need deal only with purely logical paradoxes, like that of the class of all classes which are not members of themselves, not semantic ones like 'this is a lie', which depend on the meanings of words like 'lie'. This lets Ramsey simplify *Principia*'s complex hierarchy of propositions, since it no longer needs to make 'this is a lie' ill-formed by making '*p*' and '*p* is a lie' propositions of different types. This in turn lets him drop the 'axiom of reducibility' (of propositions of higher types to equivalent ones of lower types) that *Principia* needs to validate 'many important mathematical arguments' (1990a: 190). Dropping this axiom is essential to logicism, since 'there is no reason to suppose [it] true; and if it were true, this would be a happy accident and not a logical necessity, for it is not a tautology' (1990a: 191) (see Theory of types; Semantic paradoxes and theories of truth).

In 'Mathematical Logic' (1926) Ramsey defends his logicism against 'the Bolshevik menace of Brouwer and Weyl' (1990a: 219) (see Intuitionism) and the formalism of Hilbert (see Hilbert's programme and formalism). The former he attacks for denying that all propositions are either true or false - 'Brouwer would refuse to agree that either it was raining or it was not raining, unless he had looked to see' (1990a: 228) - and the latter for reducing mathematics to 'a meaningless game with marks on paper' (1990a: 233). But he remains embarrassed by logicism's need to assume that there are infinitely many things; and R.B. Braithwaite, introducing his edition of Ramsey's papers in 1931, reports that in 1929 Ramsey 'was converted to a finitist view which rejects the existence of any actual infinite aggregate'. Despite this, and logicism's general rejection by mathematicians, Ramsey's version of it remains of great interest to logicians (Chihara 1980).

2 Probability and knowledge

If Russell and Wittgenstein prompted Ramsey's work on mathematics, Keynes prompted his work on economics and probability. The latter was provoked especially by Keynes' *A Treatise on Probability* (1921), which extends the deductive logic of conclusive inference to an inductive logic of inconclusive inference by postulating a relation

of ‘partial entailment’, knowable a priori. This, when measurable, enables a probability measure of the strength of an inference from one proposition to another. But in ‘Truth and Probability’ (1926) Ramsey attacked the idea of an a priori inductive logic so effectively that Keynes abandoned it, although it was later revived (see Carnap; Probability, interpretations of).

Ramsey’s main achievement in ‘Truth and Probability’ is his probability measure of the strength (degree) of a belief. This starts from ‘the old-established way of measuring a person’s belief, [that is,] to propose a bet, and see what are the lowest odds which he will accept’ (1990a: 68). Refining this by invoking ‘the theory that we act in the way we think most likely to realise the objects of our desires’ (1990a: 69), Ramsey derives measures both of desires (subjective utilities) and of beliefs (subjective probabilities), thereby founding the now standard use of these concepts (see Decision and game theory).

Ramsey himself uses his theory to extend ‘the lesser logic … of consistency’ (1990a: 82) from full to partial beliefs. Thus to the injunction not to believe both *p* and not-*p* he adds, for example, that anyone who believes *p* to degree 1/3 must believe not-*p* to degree 2/3. Otherwise what these beliefs will make him do ‘would depend on the precise form in which the options were offered him, which would be absurd’: that is, they would make him bet at different odds on *p* and against not-*p*, so that ‘he could have a book made against him by a cunning better and would then stand to lose in any event’ (1990a: 78).

Ramsey also uses his theory to develop ‘the larger logic … of discovery’, applied (following Peirce) to belief-forming ‘habits of inference … observation and memory’ (1990a: 92). He shows why such a habit is good or bad ‘as the degree of belief it produces is near or far from the actual proportion in which the habit leads to truth’, and hence why the fact that ‘the world is so constituted that inductive arguments lead on the whole to true opinions’ makes our inductive habits reasonable (1990a: 93).

Hence also Ramsey’s claim in ‘Knowledge’ (1929) that ‘a belief [is] knowledge if it is (i) true, (ii) certain [that is, a full belief], (iii) obtained by a reliable process … [that is, one] that can be more or less relied on to give true beliefs’ (1990a: 110). This claim anticipates later accounts of knowledge (see Internalism and externalism in epistemology; Reliabilism), showing amongst other things how we can know things we do not know we know. This in particular enables Ramsey to evade several well-known objections to knowledge, conceived of as true belief that the believer could justify, which need to assume that I can only know something if I know I know it (Sahlin 1991).

In ‘Truth and Probability’ Ramsey does not apply his subjective reading of probability to physics. Unfortunately he later, in ‘Chance’ (1928), anticipates de Finetti (1937) by taking even physical chances to be only ‘in another sense objective, in that everyone agrees about them’ (1990a: 106). To this we may reply by adding to his objection to Keynes, that determining the right probabilities ‘in molecular mechanics … is a matter of physics rather than pure logic’ (1990a: 85), that it takes more than mass psychology to explain (for example) the random decay of radioactive atoms.

Fortunately Ramsey does not make all his successors’ mistakes. In particular, unlike many later decision theorists (for example, Jeffrey 1983), he never *prescribes* acting ‘in the way we think most likely to realise the objects of our desires’. He claims only that the theory that we do so is ‘a useful approximation to the truth … like Newtonian mechanics’ (1990a: 69). Here he is right: for even when I in fact do something because ‘it seemed a good idea at the time’, this fact about my action does not suffice to make it rational.

3 Belief and truth

In defining a belief’s strength by its effects on our actions, Ramsey foreshadows later theories which define mental states by their causes, effects and interactions (see Functionalism). In ‘Facts and Propositions’ (1927) he extends this idea from degrees to contents of beliefs, taking (for example) ‘the equivalence between believing Onot-*p*O and disbelieving O*p*O … to be defined [by their sharing] many of their causes and … effects’ (1990a: 44). But after failing to define the contents of beliefs as effectively as their degrees, Ramsey concludes that his view, that ‘the meaning of a sentence [expressing a belief] is to be defined by reference to the actions to which asserting it would lead’, remains ‘very vague and undeveloped’ (1990a: 51).

It is, however, developed enough to stop Ramsey’s theory of truth being, as is usually supposed, that truth is

definable by the fact that for all *p*, it is true that *p* iff *p* (see Truth, deflationary theories of). He does say that 'there is really no separate problem of truth' since (for example) 'Oit is true that Caesar was murderedO means no more than that Caesar was murdered', so that 'if we have analysed [belief] we have solved the problem of truth' (1990a: 38-9). But the solution will not be the so-called redundancy theory if our analysis of beliefs includes a substantive analysis of their truth conditions, as Ramsey's needs to do.

Ramsey starts by observing that we can 'say that a chicken believes a certain sort of caterpillar to be poisonous, and mean by that merely that it abstains from eating such caterpillars on account of unpleasant experiences connected with them'. Since this action is 'such as to be useful if, and only if, the caterpillars were actually poisonous … any set of actions for whose utility *p* is a necessary and sufficient condition might be called a belief that *p*, and so would be true if *p*, i.e. if they were useful' (1990a: 40, see Truth, pragmatic theory of).

Unfortunately Ramsey drops this idea when dealing 'with those beliefs which are expressed in words … or other symbols, consciously asserted', although it can apply to them too. In fact its only fault is to identify a belief with a set of actions, like abstaining from eating caterpillars, instead of with one of their causes. But any theory that makes beliefs entail causal functions from desires to actions can remedy this. For then the 'set of actions' of a full belief *b* will be all those that *b* would combine with some desire to cause; and *p* will be the condition in which every such action would succeed - that is, achieve the object of the desire involved, say to eat without dying. But this is obviously the condition that *b* be true, that is, *b*'s truth condition.

Ramsey can therefore let this 'success semantics' (Whyte 1990) give the truth condition of any belief definable by 'the actions to which … it would lead'. Indeed he must do so, since a belief's truth condition cannot be given just by how it makes us act, for that will be the same whether it is true or false. What does depend on a belief's truth is whether the actions it causes succeed: hence success semantics. But this, while vindicating Ramsey's claim that analysing belief solves the problem of truth, rules out the redundancy theory: for success semantics, since its contribution to the analysis of beliefs is to say what makes them true, is itself a substantive theory of truth.

4 Laws and causation

Ramsey produced two theories of laws of nature (see Laws, natural). Both are Humean in distinguishing law statements from accidentally true generalizations not by what they say but by how we use them. In 'Universals of Law and of Fact' (1928) Ramsey says they are 'consequences of those [general] propositions which we should take as axioms if we knew everything and organised it as simply as possible in a deductive system' (1990a: 150). Although Ramsey soon abandoned this 'systematic theory' (Armstrong 1983), it remains the best Humean account of laws.

Ramsey's second theory, in 'General Propositions and Causality' (1929), is that law statements like 'all men are mortal' are 'variable hypotheticals', which 'are not judgments but rules for judging OIf I meet a I shall regard it as a Čpsi;O' (1990a: 149). Thus 'a causal generalization is not … one which is simple, but one we trust' (1990a: 150), while to believe there are unknown laws is to believe there are 'such singular facts … as would lead us, did we know them, to assert a variable hypothetical [which must] be also asserted to hold within … the scope of our possible experience' (1990a: 152).

This theory explains why we invoke causation and laws in assessing action, since 'we cannot blame a man except by considering what would have happened if he had acted differently; and this … depends essentially on variable hypotheticals' (1990a: 154). But its account of why 'the deduction of effect from cause is conceived to be so radically different from that of cause from effect' (1990a: 157) will not do. For here Ramsey relies on our view that causes precede their effects, a view he identifies with the fact 'that any present volition of ours is (*for us*) irrelevant to any past event … *to us* now what we do affects only the probability of the future' (1990a: 158; emphasis added). But this implies that the only reason we can't affect the past is that we think we can't, which is absurd. Only the fact, not the view, that effects never precede their causes can explain why gluttons should believe 'I will starve if I don't eat' but not 'I will have starved if I don't eat': *pace* Ramsey, some variable hypotheticals need to be made true by facts (see Causation; Counterfactual Conditionals).

5 Theories

Scientific theories apply new predicates to unobservable entities, like photons, to explain observable, for example

optical, phenomena. How do these predicates acquire empirical meaning? Ramsey's drastic answer in 'Theories' (1929) is that there are no such predicates: we use 'is a photon', 'has frequency *n*', and so on not as predicates but as existentially bound variables. That is, a theory tacitly starts with quantifiers, 'properties exist - call them Obeing a photonO, etc. - such that …', followed by the explicit theory, in two parts. Its *axioms* link its predicate variables to each other, while its *dictionary* (see Campbell, N.R.) links them to observable predicates like 'is red' (1990a: 112). Thus if '*a*', '*b*' and '*g*' are our theoretical predicates, 'the best way to write our theory seems to be … (∃*a*,*b*,*g*):dictionary.axioms' (1990a: 131). This, which is now called the 'Ramsey sentence' of the theory, eliminates its problematic predicates while keeping its structure and observable consequences.

Although this account has been widely accepted - and explicitly applied to functionalist theories of the mind (Lewis 1972) - its explanations of other striking facts about theories are rarely noticed. It entails for example that parts of theories, since they contain variables, are not 'strictly propositions by themselves' and their meaning 'can only be given when we know to what stock of OpropositionsO … [they are] to be added' (1990a: 131). Since this makes theoretical statements in rival theories incomparable, 'the adherents of two such theories could quite well dispute, although neither affirmed anything the other denied' (1990a: 133). This both explains the phenomenon of 'incommensurability' (see Kuhn, T.S.; Incommensurability) and limits its consequences, for example for deductive accounts of theoretical explanation (see Hempel, C.G.): for as Ramsey remarks, it does not affect reasoning within the scope of a single theory's quantifiers.

Because Ramsey sentences say that certain universals (properties or relations) exist, nominalists, who deny this, must reject them (see Nominalism). Realists about universals, however, can use Ramsey sentences to determine what empirical universals exist, as follows. Since not only *un*observable properties exist, we treat *all* predicates in law statements as variables. The Ramsey sentence of all such statements then quantifies over all universals that occur in laws, which are all the empirical universals there are (Mellor 1991).

6 Universals

What lets Ramsey ignore nominalism in 'Theories' is his denial in 'Universals' (1925) that our distinction between particulars and universals shows any intrinsic difference between them. First, it cannot be based on the subject-predicate distinction, e.g. between 'Socrates' and 'is wise' in 'Socrates is wise': for the subject of the equivalent 'wisdom is a characteristic of Socrates' is wisdom, which is not a particular (1990a: 14). Also, in molecular propositions like 'Socrates is wise or Plato is foolish', the subject-predicate distinction generates complex universals, like being wise unless Plato is foolish. But Ramsey argues that if these existed, then (for example) that a universal *R* relates *a* to *b*, that *a* has the complex property *Rb* and that *b* has *aR* would 'be three different propositions because they have different sets of constituents, and yet they are … but one, namely that *a* has *R* to *b*. So the theory of complex universals is responsible for an incomprehensible trinity, as senseless as that of theology' (1990a: 14). Similarly with Socrates' apparent property of being wise-unless-Plato-is-foolish and Plato's of being foolish-unless-Socrates-is-wise. If, as Ramsey assumes, the proposition that Socrates is wise or Plato is foolish can have only one set of constituents, there can be no such complex properties.

Predicates can therefore distinguish universals from particulars only in atomic propositions, and even then the distinction will not imply an intrinsic difference unless that difference would explain our impression that (for example) 'Socrates is a real independent entity, wisdom … a quality of something else' (1990a: 19). But no such difference will do this. For our impression comes from associating 'wise' only with propositions of the atomic form '*x* is wise' while associating 'Socrates' with *all* propositions containing it, including the molecular 'Socrates is neither wise nor just'. Yet we could as easily associate 'wise' with this and all other propositions containing it, and restrict 'Socrates' to the atomic form 'Socrates is *q*', where *q* is a universal: a form which, without complex universals, can no more include 'Socrates is neither wise nor just' than '*x* is wise' can include 'neither Socrates nor Plato is wise' (1990a: 20-1). So no intrinsic difference between universals and particulars can be inferred from - since none will explain - our associating atomic forms with predicates but not subjects.

Why then do we do that, thus making universals seem less 'real and independent' than particulars? Ramsey's explanation is this. A predicate symbol 'Čphis;' can stand alone only if it names a real universal, not if it abbreviates (for example) 'has *R* to *a* or *S* to *b*'. This we must abbreviate to 'Čphis;*x*', to distinguish it from the two-place '… has *R* to *a* or … has *S* to *b*', written 'Čphis;(*x*,*y*)'. But since it is irrelevant to an extensional logic whether or not 'Čphis;' names a universal, we always write 'Čphis;' as 'Čphis;*x*', 'Čphis;(*x*,*y*)', etc., thus

associating all predicates with atomic forms (1990a: 26-8).

We cannot therefore infer from this practice that particulars differ intrinsically from universals. A logician can take 'any type of objects whatever as the subject of his reasoning, and call them individuals, meaning by that simply that he has chosen this type to reason about' (1990a: 30). We naturally choose easily discriminable objects, such as those with locations in space and time, to quantify over first; but what makes them particulars is simply *that* we choose them, not why. But then the fact that objects of certain types fail to count as particulars, just because we choose to exclude them from the range of our *first*-order quantifiers, is no reason to deny, as nominalists do, that they exist. The existence of universals - that is, of whatever we leave for our second-order quantifiers to range over - is no more problematic than that of particulars.

Ramsey, Ian Thomas (1915-72)

Ramsey's work developed within two parameters. One concerned God and language: he held that no literal statement could be true of God; all language concerning God must be metaphorical. Another concerned his epistemology: knowledge, he held, comes ultimately from experience - sensory, introspective, but also religious. Evidence that God exists comes from experience, and claims about God must be cast in nonliteral terms.

Born in 1915, Ramsey earned firsts in mathematics, moral sciences and theology at Cambridge University. He was chaplain of Christ's College, Cambridge, from 1943, and Nolloth Professor of the Philosophy of the Christian Religion at Oxford from 1951-66. In 1966, he was appointed Bishop of Durham.

Ramsey maintained that any use of religious language needs to be understood in terms of its context. He described the experiential contexts in which the word 'God' is used as a referring term. To do this, it is necessary to map the relationships between the term 'God' (and the concept it expresses) and other terms endemic to the same context. This constitutes Ramsey's 'logical empiricism'.

In endeavouring to understand and express experiences of divine activity, believers use models. For Ramsey, in no sentence of the form 'God is… ' is the predicate term that fills in the blank used either univocally, equivocally or analogically. The relation between 'God' and the predicate term will be that between the key word of a model and a term qualifying that model. Thus his analysis of religious experience is offered in the formal rather than the material mode.

As an example of how Ramsey's account works, consider the word 'wave', which is a key term in a model used to record regularities in the behaviour of light. Otherwise isolated phenomena thereby become conceptually organized, and prediction of further regularities is possible. Second-order models organize first-order models into a comprehensive theory. Without first- and second-order models, science would be impossible.

Logical positivism and its verification principle dominated Ramsey's academic setting. The plausibility and the destructive implications of the verification principle were vastly overrated, but to be heard, Ramsey had to respond to positivism's challenge. The positivists prized formal philosophy, science and sensory experience. Ramsey offered a formal mode account of models, and an analysis of science as the task of constructing appropriate first-order reportive models and second-order theoretical models. He added that theology does for religious experience what science does for sensory experience. In both cases, the relevant story is formal, experiential and model-governed. Ramsey's view was that the nature of religious experience justified his type of approach to it, and that the approach of science to observation was analogous; thus in so far as positivist concerns were legitimate, they could be met. What Ramsey called a 'disclosure model' of some thing *X* is isomorphic with *X* (shares *X*'s structure), but shares no quality with *X* and justifies no description of *X* beyond the claim that the model and *X* are structurally analogous.

Ramsey's account of self-knowledge is central to his theory. Each of us has experiences in which we know ourselves distinctively as ourselves. In such experiences, there is self-disclosure; we apply to ourselves a model in which 'I' is the key term. We may discern ourselves in circumstances in which we fall in love, fear death, or recognize an obligation. The disclosure is to the effect that the self (construed as indescribable) bears a relation to its states in a manner structurally analogous to the relation between 'I' and 'my states' in a conceptual model in which these serve as key terms. We may experience God in situations in which we are impressed by ceaseless changes in nature or note the existential dependence of what we experience, discerning a changeless being or an independent being. This amounts to the claim that God and changing or dependent things are related to one another as the 'Unchanging Independent Cause' and 'changing dependent things' in a conceptual model in which these serve as key terms.

Ramsey, then, claimed that in our recognition of change, dependence and demise we discern the presence of something unchanging, independent and unending. He held that God cannot be described in literal terms, and endeavoured to hold these ideas together by viewing the relevant experiences as properly capturable in models whose structure (and nothing else) is ascribable to dependent things and God. Disclosure experiences are for Ramsey epistemologically primitive, needing no justification. Theological reasoning is a matter of placing

collective disclosure models, which integrate particular experiences or types of experiences, under a second-order model, and theological statements 'point to' rather than describe God.

Ramsey tried to combine a stringent empiricism with an acceptance of the cognitive significance of theology. He thought that scientific theories and Christian theology were similarly dependent on the use of nonpicturing models. His work helped keep alive a stream of philosophical theology which nearly dried up during the times of positivism's dominance, but which again flourishes today.

Ramus, Petrus (1515-72)

Petrus Ramus, for many years a professor of philosophy and eloquence at the University of Paris, wrote textbooks and controversial works in grammar, logic, rhetoric, mathematics, physics and philosophy. He was also a university reformer. His followers were prolific with commentaries, Ramist analyses of classical texts and handbooks of their own. His logical works and those of his school exercised a large influence between 1550 and 1650.

His formation was humanist, in that he attacked scholasticism and encouraged the study (and logical analysis) of classical texts, as Agricola, Sturm and Melanchthon had done. But he was far more independent-minded than them, a stern critic of the textbooks of Aristotle and Cicero, as well as an admirer of their style and intellect. His most important innovation was the method, a theory of organization which he used to simplify his textbooks. He emphasized the need for learning to be comprehensible and useful, with a particular stress on the practical aspect of mathematics. His critics would say he oversimplified. He was also a student of Gaulish pseudo-antiquities and an important proponent of the French language. His Dialectique (1555) was the first book on dialectic in French.

1 Life and educational reforms

Petrus Ramus (born Pierre de la Ramée at Cuts, near Noyon) came from a family which had lost its wealth but not its patent of nobility with the sack of Liège in 1468. He studied in Paris at the Collège de Navarre, where he took his MA in 1536, allegedly defending the thesis that ‘everything which Aristotle said was arbitrarily fabricated’. Even if this prophetic story is true, it should be pointed out that the theses chosen for MA disputations were often humorous or paradoxical. At this stage of his life, Ramus had already been influenced by Johann Sturm, who introduced the teaching of Rudolph Agricola to Paris. Ramus began teaching at the Collège du Mans, before moving to the Collège de l’Ave Maria. As a young teacher he reread the texts of the arts course and began to formulate his response to them in his earliest books *Dialecticae partitiones (Divisions of Dialectic)*, *Dialecticae institutiones (The Teaching of Dialectic)* and *Aristotelicae animadversiones (Notes on Aristotle)* (all published in 1543). These books attacking Aristotle’s approach to dialectic were condemned by the university authorities and Ramus was forbidden to teach or publish in philosophy. He turned his attention to rhetoric and mathematics, but the shortage of teachers enabled him to evade the ban, by teaching at the Collège de Presles, and he soon became head of the college. He published a new version of his dialectic under the name of his friend Omer Talon. In 1547 he was released from the ban owing to the influence of the Cardinal de Guise on the new king, Henry II. In 1551 he was named professor of philosophy and eloquence at the Collège Royal. He continued to teach and publish on rhetoric, dialectic, Latin literature, philosophy and mathematics. He became involved in many controversies with his critics, notably Jacques Charpentier, both over his attacks on Aristotle and in relation to university appointments. In 1562 he became a Calvinist. Persecution forced him to flee Paris in 1562 and 1567. From 1568 he travelled in Germany and Switzerland. He was persuaded to return to Paris in 1570, but even explicit royal protection was unable to save him from the wrath of his enemies during the St Bartholomew’s Day Massacre of 1572. That he died a Protestant martyr had considerable consequences for his later reputation. His works were massively reprinted and became very influential in Protestant parts of Germany, in Britain and in New England well into the seventeenth century.

Ramus composed several orations and prefaces on the reform of the University of Paris, in practical matters as well as in the curriculum. The main force of his curricular changes was to support and extend the growth of humanism in Paris. He wanted to purge Aristotle as well as the accretions of scholastic logic. He proposed (in 1546) that rhetoric and dialectic should be taught simultaneously, and involve composition by the pupils. Both subjects were to be illustrated through the analysis of literary texts. In 1551 he suggested a more orthodox linear syllabus, but argued for the study of mathematics and physics in the last two years (though these were also to involve literature, including Virgil’s *Georgics* and Lucretius in the final year). In 1562 he called for more practical work in physics and medicine, referring particularly to botany and dissection. Ramus’ reforms were humanist, they were methodical (in the sense of §3 below), but above all they were intended to increase the usefulness of what is learnt in the university.

2 Logic and rhetoric

For Ramus logic was the subject which organized the rest of the curriculum. Ramus published several different versions of his major works in dialectic and rhetoric, all of which were reprinted many times. Bruyère (1984) proposes five stages for the development of the dialectic; Meerhoff (1986) proposes eight for the rhetoric. Moreover, earlier versions continued to be reprinted after later ones. These facts present the student of Ramus with large bibliographical problems. It is essential to study different states of each text and to make use of the work of Bruyère, Meerhoff and Ong (1958a).

Ramus produced works of two main kinds in each subject. Where *Dialecticae institutiones* (later called *Dialectica*) is a textbook, setting out the main doctrines of the subject, *Aristotelicae animadversiones (Notes on Aristotle)* and its successors - later incorporated in the *Scholae in liberales artes (Lectures on the Liberal Arts)* - are works of controversy, attacking Aristotle’s teachings. Discoveries in the controversial works, often prompted by Ramus’ critics, are absorbed in the textbooks, and materials dropped from the textbooks often turn up later in the commentaries to the textbooks, while materials dropped from the commentaries can reappear in the controversial works. What follows is inevitably a statement of the general tendencies of Ramus’ dialectic rather than an analysis of any particular text.

Ramus aimed at clarity, simplicity and usefulness. His textbooks proceed by definition and division and they are full of examples. Ramus’ method obliged him to avoid overlaps between subjects. Accordingly a good deal of the traditional material of Aristotelian dialectic, for example the predicables and the categories, was rejected as belonging to metaphysics. For Ramus dialectic is the art of discoursing well. It consists of invention, which finds the matter for arguments through the topics (see Agricola, R. §2), and judgment, which forms arguments into propositions, syllogisms and larger structures. Within invention Ramus proceeds by a series of dichotomies to the individual topics. His list is shorter than most earlier versions; it is organized into groups and it avoids duplication. So, for example, there is no topic of definition or substance, since Ramus considers that Agricola’s new topic of subject covers the same arguments. Ramus regarded the topics as the classes of arguments (whereas his predecessors had called them the places where the arguments are found) and he left it to his examples to show how particular topical arguments function. He followed Agricola in emphasizing the usefulness of the topics and in illustrating them with passages from poetry and oratory, but he explained much less, preferring a more austere and systematic exposition.

Ramus divided judgment into axiomatic judgment, which concerns the parts, qualities, quantities and connections of the proposition (corresponding to Aristotle’s *De interpretatione*), and dianoetic judgment, which comprises the syllogism (including all three figures, and the hypothetical syllogism) and the overall shape of the piece. At first Ramus called the latter ‘disposition’, indicating a link with rhetoric and with Agricola, but later he called it ‘method’. This integration of dialectical judgment and overall organization represents an improvement on Agricola. Thus, in earlier versions Ramus sets out the imperfect method (or method of prudence) of poets and orators alongside the perfect method (from general to particular), but later the perfect method overwhelms its counterpart. In early versions of the dialectic Ramus gives a worked example of analysing a literary text into its argumentative structure, in the way Agricola had, but later this becomes part of the commentary or an exercise for the teacher. The general tendency is for the dialectic textbook to become briefer and tighter.

For Ramus rhetoric is the art of speaking well (see Rhetoric §3). It involves ornate and correct speaking and skilful delivery. Since invention and disposition belong to dialectic they are not part of rhetoric. Since correct speaking is the concern of grammar, rhetoric can begin with a discussion of the ornate, which consists of a drastically shortened account of the tropes and figures. Thus there are only four tropes (metonymy, irony, metaphor and synecdoche). Figures of diction include the rules of prose and poetic metre as well as a selection of the figures of repetition, while figures of thought are connected with the attitude of the speaker, either alone or in an imagined dialogue with the audience. The discussion of delivery is divided into suggestions on the tones of voice to be used for different effects and on suitable gestures for head and hands. Ramus carried out a thorough reduction and simplification of rhetoric. His reduced and reorganized figures are undoubtedly easier to remember, but there is also a loss of expressive force. In the rush to simplify, many valuable observations were lost along with the repetitions and the points which apply only to the Roman courtroom.

Ramus’ controversial works tend to survey selected texts from Aristotle (for dialectic), and Cicero (§2) and Quintilian (for rhetoric), pointing out what has been omitted and what is superfluous compared with a strict view

of the subject. Ramus nearly always begins by complaining that the author has not defined his subject and divided it. He often criticizes work for confused organization and for including material which is useless or which belongs to other subjects. He attacks other authors for not having written his books, rather than trying to understand what they have to say. As a result he misses Quintilian's wisdom and Aristotle's philosophical subtlety. Still, some of his remarks are well-founded: Cicero's *Orator* is badly organized; Quintilian's *Training in Oratory* does contain a considerable amount of reduplication and a good deal of material that applies mainly to Roman lawcourts; the early books of Aristotle's Organon are more metaphysical than logical, and his *Topics* is very hard to understand. It is also true that many of Ramus' criticisms are based on a consistent position outlined in his theory of method. By the end of the revisions Ramus comes to display a good knowledge of Aristotle's work, much of it owed to his opponents.

3 Method

Ramus regards method as the key to the presentation of all arts and sciences. Method first appears in Ramus' textbook in 1546 as 'the organization of different things in such a way that the whole subject may be more easily perceived and taught'. It is mainly related to the presentation of a subject and seems to derive from Ramus' former teacher Johann Sturm. Sturm had begun his 1539 commentary on Cicero's *Divisons of Rhetoric* by defining method as 'the certain, brief, correct and comprehensive way of teaching an art'. He distinguished three types of method: from general to particular, from particular to general, and by definition and division. Sturm is probably basing himself on Galen, who in turn relies on Plato's and Aristotle's remarks on method. Between them Melanchthon, Sturm, Ramus and the commentators on Aristotle's *Posterior Analytics* raised method to an issue of major significance in the mid-sixteenth century.

Ramus adopted method as the principal form of organization for an art and he developed three laws of method, which appear after 1566 and in the *Scholae*: (1) only things which are true and necessary may be included, (2) all and only things which belong to the art in question must be included, (3) general things must be dealt with in a general way, particular things in a particular way. The first two laws are mainly used to exclude material, the third to prescribe the organization of an art, from the most general principles to the most specific instances. Ramus came to see this method as the true interpretation of Aristotle's *Posterior Analytics* and himself as Aristotle's only true follower. This did not prevent him from using the laws of method to attack the content and organization of Aristotle's own writings. Equally the laws of method gave him the confidence to streamline his own textbooks, so that what began as a humanist project based on literature became (at least on the page) a structured series of definitions and divisions, almost a set of axioms, as in modern formal logic. It also enabled the whole content of a subject to be set out in the famous pictorial dichotomies which were popularized by Ramus and his followers. The austerity of his textbooks was complemented by his emphasis on usefulness and his continuing to comment on literary texts in his own teaching. Ramus' followers produced tree diagrams to express the content and organization of literary and scriptural texts. For the future Ramus increased the importance of method as a subject, emphasized the need to select material, according to what we would now call disciplinary boundaries, and encouraged the critique of Aristotle (see Logic, Renaissance §7).

4 Mathematics, physics and science

Ramus promoted mathematics. In his orations and prefaces he cited the Bible to establish the religious duty of studying mathematics and he argued that it was the oldest of the sciences. He included it in his syllabus reforms and he left a considerable part of his wealth to endow a chair of mathematics in Paris. He insisted on the practical usefulness of mathematics and argued that it should be taught in relation to practice. He proposed a new division of the subject, into the mathematics of *intelligibilia* (arithmetic, from which geometry is also derived) and the mathematics of *sensibilia* (mechanics, astronomy and optics). Although Ramus undoubtedly taught mathematics, and regarded it as an important aspect of his reforms, he did not make original contributions to the subject. He made acute criticisms of the organization of earlier mathematics texts, according to his precepts of method, but he relied on his collaborators to provide original mathematical material.

In his lectures on physics, Ramus rejected Aristotle's conception of the subject, because much of the subject-matter is not found in nature and because of Aristotle's confusions and contradictions. He wanted less on logical issues and more on problems of mechanics, astronomy and biology. Though he preferred to derive these facts from classical texts, such as Pliny's *Natural History* and Virgil's *Georgics*, he called for observation as the

basis of physics and astronomy. In particular he argued for astronomy without hypotheses, an idea which involves a rejection of traditional astronomy, and which Tycho Brahe, whom he consulted, regarded as impossible. Ramus' followers extended his methodical approach to other curriculum subjects. Theodore Zwinger produced an analysis of moral philosophy, and Johannes Freigius wrote a huge *Quaestiones physicae* (1579) which provides a systematic account of learning about the natural world (including acoustics, music, hydrography and geography), drawing on many sources besides Aristotle.

Rand, Ayn (1905-82)

Ayn Rand was a Russian-born US novelist and philosopher who exerted considerable influence in the conservative and libertarian intellectual movements in the post-war USA. Rand's ideas were expressed mainly through her novels; she set forth a view of morality as based in rational self-interest and in political philosophy defended an unrestrained form of capitalism.

Ayn Rand was born Alyssa Rosenbaum into a middle-class Jewish family in St Petersburg. Her family's expropriation by the Bolsheviks and subsequent poverty had a profound effect on her; her first novel, *We the Living* (1936), describes the tragedy of a Russian student struggling against an evil society in the 'vast prison' that was the USSR in the 1920s. Her work was marked not only by a hostility to communism but also by a strong antipathy towards any form of compromise among competing values.

Popular success came in 1943 with the publication of her philosophical novel, *The Fountainhead*, the story of an architect who refuses to compromise his independence or his integrity while good people despair in the face of evil. A deeply moral work, its theme is integrity which, for Rand, was at the root of the idea of freedom. Even greater success came with *Atlas Shrugged* (1957), Rand's final work of fiction. More explicitly political than her earlier work, it tells of the breakdown of a society of evil as the captains of capitalist industry withdraw from a world marked by political and moral corruption. As with her earlier works, the hero is uncompromising in his integrity and confidence in the value of the moral path; the bulk of the novel charts the rise of those who begin in despair. However, Rand also turns more explicitly to philosophical problems in ethics in an attempt to set morals on a more secure epistemological footing. The book contains many long philosophical speeches by characters speaking for Rand.

The popular success of her fiction brought discipleship and the 1960s and 1970s saw the growth of an 'objectivist' movement. The influence of Rand's ideas was strongest among college students in the USA but attracted little attention from academic philosophers. Her outspoken defence of capitalism in works like *Capitalism: The Unknown Ideal* (1967), and her characterization of her position as a defence of the 'virtue of selfishness' in her novel of the same title (published in 1974), also brought notoriety, but kept her out of the intellectual mainstream.

The central philosophical argument of Rand's thought is an attempt to show that the good life is itself a substantial ethical value from which may be derived important moral conclusions. In this she is self-consciously Aristotelian, although most commentators have concluded that her argument falls victim to the same difficulties, relying on a morally substantive and controversial account of human nature to generate ethical conclusions.

Rand's political theory is of little interest. Its unremitting hostility towards the state and taxation sits inconsistently with a rejection of anarchism, and her attempts to resolve the difficulty are ill-thought out and unsystematic. Of more enduring interest is her fiction, belonging to a genre she labelled 'romantic realism'. Despite her attack on altruism and insistence on the virtue of selfishness, her real concerns were the defence of the value of integrity (to the point of self-sacrifice) in the face of evil and moral despair.

Randomness

The fundamental intuition underlying randomness is the absence of order or pattern. To cash out this intuition philosophers and scientists employ five approaches to randomness.

(1) Randomness as the output of a chance process. Thus an event is random *if it is the output of a chance process. Moreover, a sequence of events constitutes a* random sample *if all events in the sequence derive from a single chance process and no event in the sequence is influenced by the others.*

(2) Randomness as mimicking chance. Statisticians frequently wish to obtain a random sample (in the sense of (1)) according to some specified probability distribution. Unfortunately, a chance process corresponding to this probability distribution may be hard to come by. In this case a statistician may employ a computer simulation to mimic the desired chance process (for example, a random number generator). Randomness qua *mimicking chance is also known as* pseudo-randomness*.*

(3) Randomness via mixing. Consider the following situation: particles are concentrated in some corner of a fluid; forces act on the fluid so that eventually the particles become thoroughly mixed throughout the fluid, reaching an equilibrium state. Here randomness is identified with the equilibrium state reached via mixing.

(4) Randomness as a measure of computational complexity. Computers are ideally suited for generating bit strings. The length of the shortest program that generates a given bit string, as well as the minimum time it takes for a program to generate the string, both assign measures of complexity to the strings. The higher the complexity, the more random the string.

(5) Randomness as pattern-breaking. Given a specified collection of patterns, an object is random if it breaks all the patterns in the collection. If, on the other hand, it fits at least one of the patterns in the collection, then it fails to be random.

1 Chance

The most common conception of randomness identifies randomness with chance. Indeed, much of probability theory and statistics does not distinguish the two. Thus for a probabilist or statistician a *random event* and an *event due to chance* are typically the same thing. Moreover, processes giving rise to such events are referred to indiscriminately as *random*, *chance*, or *stochastic* processes.

Within statistics the adjective ‘random’ assumes a technical sense when it occurs in the phrase ‘random sample’. Given a chance process, one may wish to consider not just a single random event from this process, but rather an entire sequence of such events. Such a sequence is then said to constitute a random sample if: first, the same chance process is responsible for each event in the sequence; and, second, the occurrence of any event in the sequence is unaffected by the occurrence of other events in the sequence. If the first condition is satisfied one says that the events are ‘identically distributed’; if the second, that the events are ‘independent’.

Identifying randomness with chance now raises the obvious question, what is chance? While there exists a metaphysics of chance related to causation, determinism and free will, this entry approaches chance instrumentally in terms of those processes, like coin tossing and radioactive decay, for which our best understanding is irreducibly probabilistic (see Chaos theory for comparison, where the probabilities are artifacts of underlying deterministic systems).

2 Simulation

Scientific research consists increasingly of computer simulations that generate vast amounts of data. Presumably, if scientists had sufficient time and resources to examine nature directly, computer simulations that imitate nature would be unnecessary. Practical limitations, however, seem to render computer simulations indispensable to scientific research.

A dilemma now confronts the scientist. For many purposes the data a scientist wishes to obtain should properly be the output of a chance process characterized by some well-defined probability distribution. Practical limitations,

however, often prevent the scientist from actually sampling such a process and obtaining the desired data set (imagine a scientist who desires as data the sequence of heads and tails attained by flipping a coin one billion times - the scientist will expire before the billion flips can be accomplished). In this case, the scientist will want to simulate the chance process computationally.

The dilemma then is this. On the one hand computers are fully deterministic devices - specify an algorithm, and the behaviour of the machine is fixed. It follows that any probabilistic features of the data generated by a computer simulation are strictly eliminable. Yet, on the other hand, such data are to substitute for data generated by a genuine chance process, data which cannot be characterized except in probabilistic terms. As the output of a chance process, truly random data (in the sense of §1) are supposed to defy all but *post hoc* characterizations. As the output of an algorithm the (pseudo-) random data generated by a computer simulation are fully characterized in advance. How can the twain meet?

Strictly speaking they cannot. If randomness is identified with chance, then an event is random just in case it has the right sort of causal history and it was generated by a chance process. A computer is not a chance process. Ergo the data generated by a computer cannot be random. John von Neumann summed up the matter: ‘ Anyone who considers arithmetical methods of producing random digits is, of course, in a state of sin’ (Knuth 1981: 1).

Nonetheless, the incongruity of using not merely deterministic systems, but systems whose entire behaviour can be precisely specified in advance has not dampened the proliferation of random number generators (RNGs). What then justifies using the data generated in a computer simulation in place of data generated by a chance process? In practice what happens is this. Given an RNG statisticians, as it were, set up a gauntlet of statistical tests that serve to vet it. The tests specify properties which the overwhelming majority of numerical sequences should have if they were generated by the chance process that the RNG is attempting to mimic. If the numerical sequences generated by the RNG do not have these properties, the RNG is rejected. Otherwise it is considered adequate.

Although in practice RNGs do a lot of useful work, there remains a theoretical problem in justifying RNGs in this way (which unfortunately is the only way RNGs can be justified): any RNG is only as good as the last statistical test that it passed. Indeed, history is strewn with RNGs that were for a time considered adequate, and then shown to be deficient. The problem is that we can never be sure that an RNG incorporates biases which the statistical tests we have thrown at it have simply failed to detect. This is bad. Practically speaking this means that the scientific literature may contain errors which we shall be unable to root out until appropriate statistical tests are found to detect the biases. For instance, cosmologists whose computer simulations of the early universe rely on RNGs may find their models overturned if the RNGs they employ are subsequently found to be badly biased.

3 Mixing

Take a fresh deck of playing cards and begin to riffle-shuffle them. How many riffle-shuffles are required before the deck is thoroughly mixed? Persi Diaconis has shown that seven riffle-shuffles are needed. What it means for the deck to be thoroughly mixed is that any configuration of the deck is as likely as any other. The deck starts in a specified configuration. A single shuffle mixes the deck, but not enough to break all connection with the previous configuration. Only after multiple shuffles does the configuration of the deck lose its connection with the starting configuration. At this point one says that the deck has attained a random state.

Shuffling a deck of cards is an example of a group action. Group actions provide one way of mixing things up, but not the only way. Imagine a gas concentrated in one corner of a box. The particles that make up the gas are in motion. Over time the gas will reach an equilibrium state, filling the entire box uniformly. This is an example of a dynamical system from statistical mechanics. The system starts out in a low entropy state, with the particles concentrated in one corner, and eventually reaches a maximal entropy state (an equilibrium state), with the particles evenly distributed throughout the box. The system is said to be random once it reaches the maximal entropy state (see Thermodynamics).

The preceding examples illustrate several features that are common to systems which attain randomness via mixing: (1) such a system starts out from a specified configuration that is highly ordered or constrained (for example, the opposite of what we would intuitively want to call random); (2) a mixing process (for example, a group action) acts on the system, over time continually transforming the configuration of the system; (3) eventually an equilibrium state is reached after which further mixing does not affect the equilibrium. When the

equilibrium state is reached, the system is said to be random.

It is worth noting that uniform probabilities frequently characterize the equilibrium states signalling randomness. What it means for a deck of playing cards to be thoroughly shuffled is that no configuration of the deck is more likely than any other. Shuffling has therefore randomized the deck only if each possible configuration of the deck is equiprobable. Similarly, a gas within a box has reached equilibrium if temperature throughout the box is uniform and the particles are evenly distributed. Uniform probabilities are therefore intimately connected with this understanding of randomness.

4 Complexity

Consider the following two sequences of a hundred coin tosses (heads = 1, tails = 0):

(R) 1100001101011000110111111
1010001100011011001110111
0001100100001011110111011
0011111010010100101011110

and

(N) 1111111111111111111111111
1111111111111111111111111
1111111111111111111111111
1111111111111111111111111

It seems clear that any theoretical account of randomness had better make (R) more random than (N). For instance, since (R) was obtained by actually flipping a coin whereas (N) was artificially contrived, according to the causal account of randomness sketched in §1, (R) would be random, but (N) nonrandom.

If, however, we prescind from our knowledge of the causal process responsible for these sequences, could we still distinguish these sequences in terms of randomness? We could, for instance, try to find a statistical test whose rejection region includes (N) and excludes (R), and thereby justify calling (N) nonrandom and (R) random. But for every such test it is possible to find a corresponding test whose rejection region includes (R) and excludes (N). Nor do probabilities help distinguish the sequences, since both (R) and (N), and indeed all such sequences of length 100, have the same small probability of occurring by chance, namely, 2^{-100} or approximately 1 in 10^{30}.

Starting in the 1960s a group of researchers that included Gregory Chaitin and Andrei Kolmogorov proposed a way around these difficulties (Earman 1986). Instead of characterizing randomness probabilistically, they took the very different tack of characterizing randomness computationally. What they said was that a string of 0s and 1s becomes increasingly random as the shortest computer program that generates the string becomes increasingly long. In the 1980s cryptographers proposed a variant of this characterization: a string of 0s and 1s becomes increasingly random as the most efficient computer program that generates the string requires increasingly long computation times. The first approach characterizes randomness in terms of space complexity (that is, the amount of memory the program occupies); the second, in terms of time complexity (that is, the computation time the program requires). The space complexity approach to randomness is referred to in the literature as 'algorithmic information theory'.

It is now intuitively obvious why (R) is more random than (N). The shortest program that computes (N) has the form 'repeat "1" 100 times'. On the other hand, (R) seems to have no shorter description than the string itself. (N) can be drastically compressed, (R) cannot. Thus from the point of view of algorithmic information theory (R) is more random than (N) (see Information theory).

Although complexity approaches to randomness represent a genuine advance in the theoretical study of randomness, there is a limitation to these approaches that is often lost in the initial enthusiasm: all complexity approaches to randomness are relativized to a given computational environment. What this means is that even though a sequence may be random when its generating program is running in PASCAL on a standard mainframe computer, with respect to another computational device it may be nonrandom, and vice versa. In fact, since mappings between finite sets are always computable (recursion theory on finite sets is trivial), any finite string will

be random with respect to certain programming environments, nonrandom with respect to others (see Computability and information; Computability theory).

5 Pattern-breaking

Having now surveyed four distinct approaches to randomness, one is tempted to ask whether a common thread runs through these approaches? There is a common thread, but one that at first sight will seem counterintuitive. In a dictionary definition of 'randomness', the term characterizes objects or events brought about without method, plan, purpose, forethought, pattern, principle, order or design. Random objects are supposed to be higgledy-piggledy, evincing no patterns.

But what does it mean for an object to evince no patterns? Consider a spy who eavesdrops on a communication channel in which encrypted messages are being relayed. If the spy has yet to break the cryptosystem, the encrypted messages traversing the communication channel will, as far as the spy is concerned, fail to display any patterns. Yet as soon as the cryptosystem is broken, all the patterns hidden by the cryptosystem become apparent.

The point is this: what determines the patterns that must be broken for an object to be random is not some objective feature of the world - randomness is not a natural kind. Rather, what is random depends on the patterns that are specified within a given context and that must then be broken for an object to be random. What is counterintuitive about this approach is that randomness becomes thoroughly parasitic on the patterns with respect to which it is defined. Randomness on this view does not make sense until a given collection of patterns is specified.

How then does this pattern-breaking approach to randomness relate to the four preceding approaches? For the computational complexity approach to randomness, the low complexity programs specify the patterns. For the mixing approach to randomness, far-from-equilibrium-states specify the patterns. For the simulation approach to randomness, statistical tests specify the patterns. The pattern-breaking approach to randomness also makes clear why chance is so often a dependable route to randomness: in many applications the patterns specified in advance identify a set of very small probability (for example, a full complement of statistical tests used to vet an RNG will typically designate as nonrandom only a tiny proportion of possible numerical sequences). Since small probability events are rare, chance will typically deliver objects or events that break all such patterns, that is, objects that are random in the pattern-breaking sense.

Rashdall, Hastings (1858-1924)

Hastings Rashdall was a utilitarian in ethics, an idealist in metaphysics and a Christian monotheist in religion. His history of medieval universities became a classic. His revisions of utilitarianism are an important part of the development of that ethical theory beyond its original version in Bentham and Mill. His religious metaphysic strongly opposed the influential nonmonotheistic idealism of F.H. Bradley.

Born in 1858, and educated at Harrow and New College, Oxford, Hastings Rashdall was a lecturer in St David's College (for clergy), a theology tutor at University College, Durham, chaplain and divinity tutor at Balliol College, and Fellow, tutor and dean at New College. He became a canon of Hereford Cathedral in 1910, and dean of Carlisle in 1917. He died in 1924.

In ethics, Rashdall rejected the hedonism of Jeremy Bentham and John Stuart Mill. He none the less accepted the general utilitarian perspective that Bentham and Mill developed. He agreed with them that an action is right only if it best serves (or, in the worst case, least harms) human wellbeing. But he refused to define the good that action should pursue in terms of pleasure alone; his utilitarianism is hence ideal rather than hedonistic. He held that rational moral judgments are possible concerning the moral worth of particular ends or goals, and it is these, rather than moral intuitions of general principles defining the nature of right action independently of consequences, that should be basic in moral reflection. A tendency to promote human wellbeing is part of the good that our actions should promote.

Rashdall held that there is a deep link between morality and monotheism:

> Belief in God… is the logical presupposition of an 'objective' or absolute Morality. Our moral ideal can only claim objective validity in so far as it can rationally be regarded as the revelation of a moral ideal eternally existing in the mind of God.
>
> (1907, vol. 2: 212)

In metaphysics, Rashdall was an idealist, maintaining that only minds and their states and characteristics exist, and that there are no spatially extended and consciousness-independent physical objects. Because, as Berkeley (§§3, 5-7) argued, neither secondary qualities nor primary qualities can exist without consciousness, what we refer to as matter is the perceptual content of mental states.

Our efficacious willing is the only causality that we experience, and thus order in nature (that is, among our perceptual states) is best explained by reference to a Mind that causes regularities among our experiences. By analogy with our minds, presumably that Mind also has thought, feeling and will. Each mind is a mental substance, and none is to be thought of as merely a mode of a divine mind.

In philosophy of religion, Rashdall was a monotheist, maintaining that God is a self-conscious, independently existing mental substance on whom all other minds depend for their existence. Our knowledge of God comes, not from religious experience, but from the arguments of natural theology, particularly the moral argument for God's existence, and from revelation in so far as it is supported by reason (see Religion, history of philosophy of §5). Our moral consciousness makes us aware that only if a preventable evil serves a greater good is its existence morally permissible.

Rashdall held that there are goods for whose existence evil is necessary: for example, he suggested that evolving 'highly organized beings without a struggle for existence' and training 'human beings in unselfishness without allowing the existence of both sin and of pain' was impossible (1909: 82).

It was Rashdall's contention, then, that there are goods that not even God can elicit without allowing evil. This, he said, follows from God's nature. He seems to have meant two things. First, he meant that regarding some actual goods *G* and evils *E*, '*G* exists and *E* does not' is self-contradictory and *G* outweighs *E*; some evils are allowed because they are logically necessary conditions for important goods. Second, he meant that in some manner the ground of logical necessity lies in God's nature. No divine defect was implied when Rashdall said that it follows from God's nature that not even God can elicit certain goods without also allowing evil. God, being good, would not have created at all if evil were going to triumph.

Rashdall was a determinist: he held that human actions occur as the result of factors over which their agents have no effective control. Hence the existence of evil cannot even in part be ascribed to free and wrong human choices. God, however, is not blameworthy for the evil in the world, for God must allow certain evils in order for there to be certain goods.

Rational beliefs

To the extent that a belief is rational, it ought to be held, other things being equal; irrational beliefs should not be held. From traditional epistemological perspectives, the obligation here is narrow, concerning only good reasons for acceptance that constitute sufficient justification or warrant. Recent epistemological trends broaden the viewpoint to include also practical considerations that enter into other rational decisions, such as best use of the agent's limited resources.

A related but weaker conception of rationality appears in philosophy of mind as a necessary coherence requirement on personal identity - roughly, 'No rationality, no agent'. Such agent-constitutive rationality standards are more lenient than normative epistemic standards, since agents' belief sets can and often do fall short of epistemically uncriticizable rationality without the agents thereby ceasing to qualify as having minds.

Finally, at the widest perspective, long-standing sceptical lines of challenge to rationality of the entire structure of human belief-forming procedures conclude that we can never have the slightest good reason to accept even our most central beliefs. Recent approaches that 'naturalize' epistemology into a branch of science tend to exclude such general doubts as insignificant or meaningless; but if distinctively philosophical questions in fact do not fully reduce to regular scientific ones, sceptical-type rationality challenges may instead remain a permanent part of the human condition.

1 A priori belief

What rational belief is can be best conveyed through some major types of example. The simplest, and most extreme, case of irrationality is accepting a proposition that is inconsistent. Indeed, attribution to a person of such irrationality has sometimes been regarded as self-defeating, in that we purportedly cannot even make sense of so severe a reasoning failure. In this way charity principles of Quine and Davidson dictate that 'better translation imposes our logic' - and our rationality generally - upon the beliefs of any agent we undertake to interpret (see Charity, principle of §4). Such in-principle exclusion of the very possibility of inconsistency may seem like an overreaction, since human beings (unlike God) must often lack the insight to identify the less obvious inconsistencies in propositions they accept. To idealize away these failures as mere occasional, corrigible slips is to deny a basic fact of existence for a finite creature, human or otherwise, and to deny much of the project of the deductive sciences. We understand all too well how Gottlob Frege could genuinely accept his axioms for naïve set theory, even though they turned out to harbour Russell's Paradox; inconsistency is always with us (see Frege, G. §§8-9; Russell, B. §4).

Granting the possibility (indeed, pervasiveness) of inconsistencies, they are, as paradigmatic irrationality, conventionally viewed as disasters to be avoided or remedied at all costs. As Frege responded to Russell on the status of inconsistent foundations of mathematics, 'Arithmetic totters'. Indeed, the history of the rise of modern logic can be viewed as conditioned in large part by the discovery of, and response to, the paradoxes. However, in contrast to the traditional picture of antinomies as symptoms of disease, alternative accounts have emerged along the lines of Wittgenstein's apophthegm, 'A contradiction is not a germ which shows a general illness'. Some of these go further, to propose that inconsistency may in fact sometimes be positively healthy, as in the familiar way that inconsistent naïve set theory can be easier to use for informal purposes than later, more complicated formulations devised to avoid the paradoxes.

Psychological studies of recent decades provide some evidence that everyday human reasoning - inductive as well as deductive - might be formally incorrect to a surprising extent (see Rationality of belief; Common-sense reasoning, theories of). From the perspective of more 'realistic' theories of rationality that take account of an agent's actual cognitive processes and resources, such incorrectness need not be mysterious reasoning pathology. Such local irrationality could be made sense of as the trade-off cost of a globally rational strategy to avoid cognitive paralysis: use of 'quick but dirty', formally incorrect heuristic procedures that are more computationally efficient in many contexts than formally adequate ones can be. These accounts suggest that human beings have a multiplicity of overlapping special-purpose reasoning strategies - some formally correct, some not - that they can switch among. In this way, reasoning is evaluated in terms of, not only preservation of truth, but also wider practical issues of, for example, actual human usability of procedures given a limited cognition-budget. Paradoxes

such as Russell's then appear not necessarily as symptoms of dysfunction at the core of the human conceptual scheme, but rather as signs of fundamentally rational speed-reliability trade-offs.

2 A posteriori belief

For the empirical domain, accounts of rational belief develop along lines independent of, but still parallel to, the evolution of accounts for a priori belief. At the start of modern epistemology, Descartes proposes among rules for direction of the mind, 'I should hold back my assent from opinions which are not completely certain and indubitable just as carefully as I do from those which are patently false' (Descartes [1641] 1984: 12). He then points out that, for any belief, wide-scale sceptical doubts are always possible that would undermine any of my reasons for accepting it - for example, I might be experiencing a perfectly realistic hallucination rather than anything of a mind-independent world. Consequently, Descartes recommends a method of universal doubt, reconstructing our entire belief system from a blank slate; rational belief-management strategy must start by rejecting everything (see Descartes, R. §4; Doubt §2). However, history's majority verdict seems to be that universal doubt is not in fact advisable, that it would leave us in an epistemological tragicomedy of total, irreversible cognitive paralysis, which is rarely a rational option (see Scepticism).

Pragmatism first introduces and defines itself in terms of rejection of the Cartesian programme. Its inventor, C.S. Peirce, proposes instead 'critical commonsensism': while no belief can be immune to doubt, we can never begin with suspension of all our beliefs (see Commonsensism). From this anti-Cartesianism stems a neo-pragmatist leitmotif of much epistemology of the twentieth century. Quine (1960), for example, following Neurath, explains that Cartesian universal doubt is not only a psychological impossibility for human beings, but also self-defeating because self-undermining; to try to practise it is from the outset to sink the scientific-philosophical enterprise. The thesis that, while we must begin from whatever belief scheme with which we find ourselves, any belief can still be doubted, raises a natural next question: *Which* beliefs ought in fact to be challenged, and when?

One line of reply is that an agent is held responsible for ruling out those counter-possibilities to a belief that satisfy a 'special reasons requirement': specific, relevant ones that there is definite basis for thinking might now apply. In an example of J.L. Austin's, normally it would be humorous to criticize as hasty someone's belief that there is a goldfinch in the garden on grounds that he had not checked that the objects he glimpsed were not stuffed toys - unless, for instance, he had already been in a position to find out the neighbours' children had lately been playing with toy birds. In this way, epistemic responsibility resembles traditional doctrines of general culpable negligence, of legal responsibility for taking the due care in actions that a 'reasonable person' would. However, a thesis that the epistemic agent must take due care that falls somewhere between total irresponsibility and perfection in turn raises questions about how particular levels of required vigilance are set. Just because people in certain situations are in fact found subject to criticism if they do not maintain certain levels of care does not completely answer this question - unless actual practices are guaranteed to be optimal (see §3 below).

Thus, there has been an evolution from a simple if perfectionistic view that beliefs cannot be rational if *any* challenges to them are imaginable, to a more realistic or pragmatic type of account, where rationality of beliefs is subject to challenge only when a circumscribed set of appropriate counter-possibilities can be raised. However, if the agent is responsible for eliminating challenges whose seriousness is obviously implied by the current belief system, then formation of new rational beliefs crucially depends upon the agent's current background beliefs. Yet the background belief-set must inevitably be incomplete, particularly at cutting edges of the belief system, themselves inevitable for finite creatures like ourselves. And so breakdown scenarios can still arise where appropriateness of a counter-possibility cannot be evaluated. Even if recognition of a counter-possibility-filter in our knowledge-gathering processes may block the traditional embarrassment of sceptical paralysis, history still threatens to repeat itself in a new guise.

3 Philosophy, science and ordinary life

More generally, we seem unable to avoid posing distinctively philosophical challenges regarding adequacy of our doubt-screening procedures themselves. A question inappropriate in ordinary or scientific contexts may still not be inappropriate *simpliciter*. Rationality consists of more than just playing according to the rules of our belief-forming games; an essential part of rationality concerns the advisability of deciding to play the games in the first place. Recognition of the latter type of rationality-domain can be discerned in Kant's distinction between the

concepts of (scientific) understanding and the extra-scientific ideas of reason that guide the scientific enterprise (see Kant, I. §§6-7), in Carnap's separation of internal questions of science from external questions concerning acceptance of a whole framework for settling internal questions (see Carnap, R. §5), and in Kuhn's distinguishing 'normal' scientific activity from debate about paradigms or disciplinary matrices within which that activity proceeds (see Kuhn, T. §§2-3). *Prima facie*, we seem able to put our most basic knowledge-gathering mechanisms themselves in question and ask whether the actual is the ideal: just because a procedure is part of the system we in fact actually use, does it follow that the procedure must be perfect or otherwise uncriticizable?

One response to the intractability of such philosophical questions is to make a virtue of necessity, and to exchange impending scepticism for relativism. Basic principles cannot themselves be rationally justified without courting circularity; hence, their acceptance can be no more than a matter of epistemic taste, about which ultimately one cannot dispute or judge (see Cognitive pluralism §2; Epistemic relativism). Our own procedures may happen to be the only ones we have encountered, but they ought not to serve as a Procrustean Bed into which genuine cognitive differences must be forced. Without parochial a priori constraints on rationality, possibilities for radical cognitive diversity become wide open. However, questions in turn arise about whether radical relativism itself can even be coherently articulated. In their extreme form, these concerns tend towards a conservative conclusion that also aims to block sceptical-type challenges. One recurring argument to this effect (used, for example, by Quine) is that there is no cosmic exile from which we can take the God's-eye view required to evaluate our own basic conceptual scheme; we need a *pou sto*, a standpoint from which and by which to judge our scheme, and our actual one is the only one we have. External questions perforce become internal (see Rationality and cultural relativism).

However, one reply has been that, while we may have to employ the only system we possess, our system itself may furnish the basis for large-scale doubts about its own adequacy. For example, 'naturalized' epistemology seeks vindication of our actual procedures in a core part of the scientific worldview, evolutionary theory: natural selection has engineered cognitive structures of human beings just as it has the biological structures, and the validation of our belief-forming systems is that evolution has designed them to function well. But then in turn a natural concern is that what is efficient for information-processing tasks conducive to survival need not be epistemically sound - for instance, as mentioned in §1 above, speed and correctness are often outright antagonistic. Thus, naturalism can engender its own challenges to our scheme; such self-evaluations do not guarantee happy endings. Apparently, when sceptical challenges are eliminated by attempting to assimilate distinctively philosophical questions to those of science or ordinary life, they reintroduce themselves in new form. In this way, articulation of our conception of rationality seems a task never completed, only set aside.

Rational choice theory

Rational choice theory is the descendant of earlier philosophical political economy. Its core is the effort to explain and sometimes to justify collective results of individuals acting from their own individual motivations - usually their own self interest, but sometimes far more general concerns that can be included under the rubric of preferences. The resolute application of the assumption of self-interest to social actions and institutions began with Hobbes and Machiavelli, who are sometimes therefore seen as the figures who divide modern from early political philosophy. Machiavelli commended the assumption of self interest to the prince; Hobbes applied it to everyone. Their view of human motivation went on to remake economics through the work of Mandeville and Adam Smith. And it was plausibly a major factor in the decline of virtue theory, which had previously dominated ethics for many centuries.

Game theory was invented almost whole by the mathematician von Neumann and the economist Morgenstern during the Second World War. Their theory was less a theory that made predictions or gave explanations than a framework for viewing complex social interactions. It caught on with mathematicians and defence analysts almost immediately, with social psychologists much later, and with economists and philosophers later still. But it has now become almost necessary to state some problems game theoretically in order to keep them clear and to relate them to other analyses. The game-theory framework represents ranges of payoffs that players can get from their simultaneous or sequential moves in games in which they interact. Moves are essentially choices of strategies, and outcomes are the intersections of strategy choices. If you and I are in a game, both of us typically depend on our own and on the other's choices of strategies for our payoffs.

The most striking advance in economics in the twentieth century is arguably the move from cardinal to ordinal value theory. The change had great advantages for resolving certain classes of problems but it also made many tasks more difficult. For example, the central task of aggregation from individual to collective preferences or utility could be done - at least in principle - as a matter of mere arithmetic in the cardinal system. In that system, Benthamite utilitarianism was the natural theory for welfare economics. In the ordinal system, however, there was no obvious way to aggregate from individual to collective preferences. We could do what Pareto said was all that could be done: we could optimize by making those (Pareto) improvements that made at least one person better off but no one worse off. But we could not maximize. In his impossibility theorem, Arrow (1951) showed that, under reasonable conditions, there is no general method for converting individual to collective orderings.

After game theory and the Arrow impossibility theorem, the next major contribution to rational choice theory was the economic theory of democracy of Downs (1957). Downs assumed that everyone involved in the democratic election system is primarily self interested. Candidates are interested in their own election; citizens are interested in getting policies adopted that benefit themselves. From this relatively simple assumption, however, he deduced two striking results that ran counter to standard views of democracy. In a two-party system, parties would rationally locate themselves at the centre of the voter distribution; and citizens typically have no interest in voting or in learning enough to vote in their interests even if they do vote.

The problem of the rational voter can be generalized. Suppose that I am a member of a group of many people who share an interest in having some good provided but that no one of us values its provision enough to justify paying for it all on our own. Suppose further that, if every one of us pays a proportionate share of the cost, we all benefit more than we pay. Unfortunately, however, my benefit from my contribution alone might be less than the value of my contribution. Hence, if our contributions are strictly voluntary, I may prefer not to contribute a share and merely to enjoy whatever follows from the contributions of others. I am then a free-rider. If we all rationally attempt to be free-riders, our group fails and none of us benefits.

A potentially disturbing implication of the game theoretic understanding of rationality in interactive choice contexts, of the Arrow impossibility theorem, of the economic theory of democracy and of the logic of collective action is that much of philosophical democratic theory, which is usually normative, is irrelevant to our possibilities. The things these theories often tell us we should be doing cannot be done.

1 Historical background

Of course, the role of self interest in explaining behaviour was not a discovery of the Renaissance and Reformation. From Socrates to the beneficent utilitarians, interest has been of central concern. Indeed, it has long been common to view morality as action against one's own interest in the interest of others or for otherwise good ends or good reasons. For example, Sidgwick saw beneficence and self-interest as often contrary dual motivations. Machiavelli and Hobbes were merely more insistent than many earlier philosophers on seeing the world as dominated by self-interest, and they were less ready to salvage social order in theory by supposing individuals just would or do behave well or public spiritedly.

The history of the slow invention of rational choice theory may be best told in the account of the role of fallacies of composition in political philosophy. Such fallacies in the aggregation from individual to collective choice or good are a standard background problem for rational choice theory. We are guilty of a fallacy of composition when, without argument, we assume that the attributes of an entity are the attributes of its constituents. This is a form of metaphorical or analogical reasoning that might sometimes yield correct results, but it often leads us astray. For example, we argue from the premise that every individual is rational to the conclusion that a nation or a group of individuals is rational in the same sense. It is only a slight exaggeration to say that rational-choice political theory is essentially an effort to block conclusions that are fallacies of composition. The three biggest bodies of work in rational-choice political theory - the aggregation of individual into collective preferences in the Arrow problem (§4), the rational-choice theory of voting and democracy (§5), and the logic of collective action (§6) - are deflations of fallacies of composition, as is the prisoner's dilemma game (§3), which is related to the collective action and voting problems.

Perhaps the central claim in Socrates' political philosophy is that it is in an individual's interest to act justly, to be just. This claim contradicts appearances that we, Glaucon in Plato's *Republic*, and others cannot deny. Socrates denies that there is a fallacy of composition in going from what is best for the individual to what is best for the community. It takes a great deal of devious argument and an adoring audience for him to seem convincing. Many teenage university students have since been hectored into accepting Socrates' conclusion and have therefore misconceived politics and group action from the beginnings of their supposed understanding. Perhaps it does not take more hectoring than it does merely because the fallacy is remarkably easy and seemingly natural.

After Socrates, Aristotle began his *Politics* with his own variant fallacy of composition. He supposed that, because every man acts with the intention of producing something that is a good, the polis, the most sovereign association of men, must pursue the most sovereign of goods. Aristotle's views have often been taught less with hectoring than with the weight of authority, but they too have set beginners on the path of confusion. Long after the reign of Greek philosophy, Aristotle came back into favour in a church that secured a match between individual interest and morality by inventing everlasting punishment for immorality. In effect, the church established a causal connection between individual and collective good to replace the failed conceptual connection. The causal connection it created was to make full use of self-interest.

Eventually Hobbes and others demolished the fallacy of composition at the heart of Socrates' and Aristotle's claims. In his allegory of the state of nature, Hobbes explicitly supposed that individuals would follow their own interests and that the result would be collective misery. This result gave licence to his invocation of an all-powerful governor to bring harmony and wellbeing because it can generally be in my interest to act well toward others only if there is a government prepared to coerce both me and the others to behave well. In three short chapters (*Leviathan*, chapters 13-15) Hobbes laid the foundations for rational choice theory and for political philosophy thereafter. A rational choice theorist might finally wish to say that Hobbes is the first modern political philosopher because he was the first to recognize and be persistent in avoiding fallacies of composition inherent in much of political philosophy before him (and, alas, since).

Nearly a century after Hobbes, Mandeville (§3) argued that private vices beget public virtues. In particular, universal avarice produces wide prosperity. This is a grim thought for virtue theory. All of us must wish others were avaricious because then they would serve our interests well. Avarice, the worst of all vices, has good results and its contrary virtue might have bad results. Smith, after writing his own book of near-virtue theory, *The Theory of Moral Sentiments*, then went on to write an economic theory in *The Wealth of Nations* that matched Mandeville's and severely undercut virtue theory (see Smith, A. §3). The central move, again, was to cut the supposedly conceptual connection between self interest and collective interest. There could be no conceptual, but

only a causal, connection, if any.

2 Game theory

Game theory is typically not about the source of the incentives we face but about the force of them, as is also true of rational-choice theory more generally. For most of its use, game theory is applied to actual payoff structures or to idealized structures. The payoffs are simply given. An economic theory of knowledge and preference formation can be brought to bear to explain preferences and, hence, to determine payoffs.

In social thought and in rational choice theory, games may be associated with three broad classes. There are games that involve pure conflict, games that involve pure coordination, and games that mix these two. If the only way for you to do better is for me to do worse, as when we play chess, we are in a game of *pure conflict*. If the way for each of us to do best is for both of us to do the same thing (in some sense), we are in a game of *pure coordination*, as when we drive our cars in North America and hope that every other driver stays to the right as we do (or in the UK, to the left). If I can sometimes do better only when you do worse and sometimes we can both do better by doing the same thing, we are in a *mixed-motive* game, which involves a mixture of conflict and coordination.

These three kinds of game can be represented very simply in two-person formats; each intersection of strategy choices yields a pair of payoffs. The first payoff in each pair is to Row, the second is to Column. The payoffs here are ordinal, with 1 as the first (best) choice, 4 the last (worst) choice. In the coordination and mixed-motive games, each player has two strategies from which to choose. In the pure conflict game, Column has no choice but will get whichever payoff Row chooses.

There could be any number of strategies available to both players in all categories of games. Moreover, the payoffs could be in almost anything, such as money, position, goods, or abstract utility. In most of social theory and of rational choice theory, ordinal games are adequate because there is no good sense of any quantity that could cover the range of payoffs. Even in games in which one might state what the payoffs are in each cell, one might be unable sensibly to assign them weights in anything like monetary or utility terms, so that ordinal representations still are adequate. However, ordinal representations lose important information that might alter the way people choose in a game, for example if the difference between one's first and second ranked outcome is trivial while that between the second and third is enormous.

Game theory first grew out of games of pure conflict (see game 1), perhaps especially on the model of poker. In a pure conflict game there is nothing to be gained by cooperation. When there are more than two players, there is typically the possibility of cooperation that makes the game not pure conflict. Then the analysis of the game becomes an analysis of coalitions of players that can form. Poker can be played under rules that block collusion or cooperation between players, and other games can be contrived that have more than two players but that are still games of pure conflict between every pair of players. Von Neumann's saddle-point or *maximin* theorem for two-person pure conflict games shows that one cannot do better against a symmetrically rational player than to choose a strategy that includes the so-called maximin payoff. That payoff is the best of the set of worst payoffs one could get from each strategy choice, or the maximum minimum (see Neumann, John von).

Game 1. Pure conflict

	Column	
	I	II
Row		
	II	2,1

One might think that pure conflict games are a very large and important class for social interaction. However, most social interactions that seem superficially to be pure conflict actually involve extensive opportunity for mutual benefit. For example, war might be seen as a game for victory or defeat, an analogue of chess. But actual wars, other than wars of attempted annihilation, can be fought in restricted ways that make all potentially better off. Hence, there is room for coordination as well as conflict.

Virtually the opposite of games of pure conflict are games of pure coordination, in which the incentive is to achieve harmony. Indeed, these games have been called common-interest games. Harmony can often be achieved without communication or anything even vaguely approaching agreement. The players need only recognize that their jointly best payoffs are in one or more outcomes and that there is some reason for choosing some particular strategy that includes one of those outcomes. If I am playing you in game 2 without opportunity for communication, I might choose strategy I instead of strategy II simply because the I-I outcome would come first for anyone reading English, which starts at the top left of the page - and I presume you might think the same way. Thomas Schelling (1960) has shown that people are remarkably good at coordinating in such ways without conversation.

Game 2. Pure coordination

		Column	
		I	II
	I	1,1	2,2
Row			
	II	2,2	1,1

In the pure coordination game of game 2, note that there are two outcomes with equally good payoffs for each player. Row does not care whether Column chooses strategy I or strategy II, but only cares whether both of them choose strategy I or strategy II. So long as they both choose the same strategy, they do well. Because there are two possible coordination outcomes, it is possible for the players to miscue and to finish in one of the second best payoffs. Hence, even pure coordination problems, as sanguine and simple as they may seem, can pose difficult personal and social choice problems. When such games in practical life are iterated, they are often resolved by convention (Hume 1739-40; Lewis 1969). Once we reach one of the best outcomes in an iterated class of interactions, we thereafter stick with the successful strategy, thereby establishing a *convention*.

3 Mixed-motive games

The mixed-motive game of game 3 merits extended discussion. The mixed-motive category includes many strategically distinct games. Game 3 is specifically a variant of the prisoner’s dilemma game, which is by far the most studied of all games. In the 1960s it captured the imagination of social psychologists, for whom it became a lasting focus of research. It is central in theoretical and simulation studies of altruism. And it has been associated more generally with the problem of collective action (§6). Despite all the attention it has got, however, it may have been relatively neglected in many circles because it has a misleading name.

Game 3. Mixed motive (Prisoner's dilemma or exchange)

		Column	
		Cooperate	**Defect**
	Cooperate	2,2	4,1
Row			
	Defect	1,4	3,3

As can be seen from the order of payoffs in game 3, prisoner’s dilemma has two striking features that suggest a conflict of motivations for the players. Suppose you are Column and I am Row. You can readily see that you rank your payoff from defection higher than your payoff from cooperation no matter what I do. If I cooperate, you get your best outcome in defecting. If I defect, you get your third best rather than your fourth best if you defect.

Hence, you have a *dominant strategy*: defect no matter what. My position is symmetrically equivalent to yours, so that I have the same dominant strategy. If we both follow our dominant strategy, we both defect and we reach an *equilibrium* in the game. But it is also obvious in game 3 that we both will be better off if we both cooperate than if we both defect. If we have any device outside the payoffs of game 3 to enable us to contract to insure mutual cooperation, we would benefit from doing so.

The prisoner's dilemma is unique among the seventy-eight strategically distinct two-person ordinal games in that it has an equilibrium that is Pareto inferior to some other outcome (Rapoport and Guyer 1966). (One outcome is Pareto inferior to another if moving from it to the other makes at least one person better off while hurting no one.) Defection dominates cooperation individually but mutual cooperation is better than mutual defection. The crossed incentives are maddening. But they are nothing new - we face them daily in our lives. Moreover, resolving their large-number analogue is the crux of political order (§6).

The discoverers of prisoner's dilemma were Flood and Dresher at the Rand Corporation around 1950. Flood had been trying to represent the sale of a used car as a game. Perhaps from a sense of that game's peculiarity, he and Dresher then designed the original prisoner's dilemma to test how people involved in an interaction repeatedly would behave. In essence, the first prisoner's dilemma experiment was of an iterated game. The game was sufficiently peculiar in comparison to other games, as noted, that they showed it to many people, including the Princeton mathematician, A.W. Tucker, speculating on what it might mean or represent. Tucker proposed the morality tale of two prisoners caught up in the American legal system. Kept in separate rooms, the prisoners are offered a chance at a reduced sentence if they will turn state's evidence against their partner. If both turn state's evidence, both will get lighter than the maximum sentences. If only one does, the other will get the maximum sentence, while the confessor will get a very light sentence. If both refuse to talk, both will get a mild sentence for a corollary crime (illegal possession of a firearm). The individual incentive is to turn state's evidence, but the prisoners could jointly do better if they both keep silence. The terms 'cooperate' and 'defect' correspond, for the prisoners, to keeping silence and turning state's evidence.

Unfortunately, this story of the two prisoners seems to have been more captivating than the game. Yet the real structure of that game is so common in life that, had it been properly identified in its name, it might have entered political philosophy and economics a decade or two sooner. In its payoff structure, prisoner's dilemma is fundamentally the model of ordinary *exchange*. The tale of two prisoners blurs the generality and import of the game. As is instantly obvious from their identical payoff structures, the morality tale of two prisoners and ordinary exchange are *strategically* identical. If there are morals to be drawn, they will first have to be inserted.

A particularly important variant of the prisoner's dilemma is the game in iterated play. When you and I are in an interaction beyond the immediate play of the game, we might both have incentives for action that derive from the further interaction as well as from our immediate game structure. In general, we may expect to see cooperative play in a prisoner's dilemma that is iterated many times, even into the distant future. Because much of our social life involves ongoing relationships, we will be able to map it into game theory only through iterated games. If the prisoner's dilemma is played once only between players who do not expect to meet again and without external constraints that would, for example, permit enforceable contracts, then virtually all game theorists think the players should rationally defect. What we face in real life commonly violates these pristine conditions enough to make it our interest to cooperate in manifold exchange relations (Hardin 1982; Axelrod 1984).

Game theory is a natural ground on which to investigate the plausible meaning of rationality in interactive choice. The standard statement is that it is rational to maximize (or optimize) one's own payoff against another player (or other players) who simultaneously maximizes. This is a patently circular or self-referential definition. But it sometimes works, as in pure conflict games. It also sometimes fails, as in many mixed-motive games. When it fails, we are left free to proclaim various solution concepts for games because we cannot stipulate that a particular one is rational in this natural but circular sense - and the literature is cluttered with variant solution concepts. We might conclude that rationality is ill-defined and merely wants more analysis. But we might sooner conclude that rationality is inherently indeterminate in many interactive choice contexts.

Note also that rational choice in the context of strategic interaction does not fit well with much of philosophical action theory. In philosophical action theory, I typically produce outcomes directly from my own action. My action when I choose one strategy rather than another is, of course, motivated by my concern with outcomes. But

the choice and the outcome are not directly connected. Rather, the outcome is the joint result of choices of strategy by me and by as many others as there are in the interaction. I might choose a strategy that includes some dreadful outcomes because my choice joined with strategies that I expect others to choose would produce a very good outcome. In the terminology of rational choice and standard decision theory, when I do not choose against nature but choose in combination with others with whom I interact, the meanings of my choices can be very complex.

4 The Arrow problem

The basic move from cardinal to ordinal value theory was completed in the 1930s when J.R. Hicks and R.G.D. Allen (1934) worked out the formal structure of an ordinal theory that could then be put to work in standard economic accounts. The next challenge was to move from Benthamite aggregate welfare to ordinal social welfare, still based on aggregation from individual, but now ordinal, preferences. Arrow took on this problem with the apparent expectation of resolving it positively. In a retrospective account, Arrow (1983) implicitly acknowledged that he had expected to demonstrate that it was not a fallacy of composition that we could move from individual to collective preferences of the same kind. Instead, he soon showed that it was a fallacy of composition and that Pareto was *de facto* right. He proved what is now called Arrow’s *impossibility theorem*: that there is no general way to aggregate individual ordinal preferences into collective ordinal preferences over the possible whole states of affairs.

The limited Pareto principle is often indeterminate because in many social contexts all plausible changes would make someone worse off and because, when there is more than one available Pareto improvement (a common state of affairs), the Pareto principle typically cannot say which is better. Similarly, ordinal social choice is indeterminately related to individual preference.

Arrow’s theorem is based on several assumptions that sound relatively benign and acceptable. First, he stipulates that only ordinal preference rankings be considered (the ordering condition, O). Then he stipulates that no individual’s preference ordering will be the ordering of the society (nondictatorship, D), no restrictions can be placed on any individual’s choice of orderings (universal domain, U), if everyone prefers one state of affairs to another, society prefers that state to the other (unanimity or Pareto, P), and if individuals’ rankings over the social choices are changed but no individual reverses the order of two possible choices, then the collective ordering over those two choices cannot change (irrelevance of independent alternatives, I). Finally, he implicitly assumes, reasonably enough, that our society has a finite number of individuals.

One might quarrel with each of these assumptions. But there is no point in quarrelling with O, since it is the point of Arrow’s exercise. There is also no point in quarrelling with Arrow’s unstated but implicitly invoked condition of finitude of the citizenry. And few have ever quarrelled with condition D - except to suggest it be made even stronger. Similarly, few argue against condition P, although Amartya Sen (1970) has campaigned hard against it. It is easy, however, to imagine states of affairs that everyone would rank below some other state (thus violating U). And many, perhaps most, commentators do not really know what to think of condition I. Is it naturally compelling? Or does it merely represent the lazy way we think through the problem of aggregation? In his own proof of the impossibility theorem, Arrow did not explicitly invoke the condition - although he did implicitly assume it.

As will be discussed further in §9, there is another fundamental issue that seems bothersome for Arrow’s theorem: the ranking of whole states of affairs. As Arrow says, a whole state of affairs means everything is determined. We can avoid the burden of such inclusiveness only if ordinal preferences over some things can be stated with a *ceteris paribus* clause that declares these things to be decoupled from all else. Why? Because ordinal preferences resolve two important and nearly intransigent problems of the older cardinal value theory. Under the older theory, I should apparently value two dinners tonight at twice the value of one - but clearly I do not. Indeed, I might even pay not to have to eat one of them. The two dinners would be *substitutes* for each other and therefore the second one need add no welfare to me. Also under the older theory, I should apparently value anything independently of what else there is or what else I have - but this is patently false. Some things are *complements*, and their value might be enhanced or reduced by my having something else with them, as my dinner and my glass of wine might be better enjoyed jointly than separately.

Now if the value to me of some consumption depends on whether there are substitutes or complements in my

bundle of consumptions, I cannot rank some part of the whole package. I can only rank whole packages in comparison to other whole packages. That is, as a citizen, I can only rank whole states of affairs fully determined.

Despite this relatively daunting thought, there is a reduced form of Arrow's theorem that is of great practical importance. It was recognized by the Marquis de Condorcet and by C.L. Dodgson. It is called the Condorcet paradox or the problem of cyclic majorities. If three or more people must choose from three candidates by majority rule, candidate A can defeat B, B can defeat C, and C can defeat A. There is then no outright majority winner (see Condorcet §2). Many voting systems in wide use avoid this problem by various random or controlled devices that sometimes bias outcomes. For example, legislatures commonly consider amendments to a piece of legislation one at a time. An amendment that wins a majority vote is added to the legislation; one that loses is dropped from further consideration. In the end, there is a decisive vote for or against the amended legislation, which is pitted only against the *status quo* and not against other possible variants. The *status quo* is therefore given privileged status because, if there are cyclic preferences over the *status quo*, the final piece of legislation and the same legislation with an alternative amendment, the *status quo* wins by virtue of not having to face the alternative. One might wish to say this is the best of plausible resolutions. But one cannot say any such thing with coherent meaning - that is the point of Arrow's theorem. Our presumptive notions of 'the best' are vacuous in this context.

5 Voting and democracy

Game theory and Arrow's theorem were very slow to enter debates in political philosophy and political science. Downs' economic theory of democracy, however, immediately became the starting point for most subsequent debate. Again, there are two main results of the theory. First, candidates, needing a majority of votes for election in two-party contests, would have to locate themselves near the middle of the range of popular preferences. Hence, in a catch phrase of 1950s US politics, the Democratic and Republican parties put up candidates who were close twins, Tweedledum and Tweedledee. This tendency inspired a massive literature on so-called responsible parties, a literature that argued that parties must emphasize their differences and must take strong positions. Downs' theory virtually killed that literature.

Second, the more crucial deduction was that voters have little interest in actually voting if the act of voting has real costs associated with it. If there are millions of voters and victory goes to the majority candidate, then my vote has little or no chance of affecting the outcome. Indeed, if elections were as close as a single vote, they would sometimes be voided and repeated simply because the counting of votes could not be accurate enough to yield a determinate outcome. But, in any case, genuinely close elections are extremely rare above the level of minor local offices. Hence, to weigh the value of my vote to me in affecting policies in my interest, I must discount my vote by the exceedingly low probability that it could matter. Its discounted value to me must be vanishingly small. This is the benefit side of my vote. Now consider the cost side. Suppose it takes a couple of hours out of my hard day for me to vote. This cost is not vanishingly small. On balance, it is therefore unlikely to be in my interest to vote.

Suppose voting costs could be reduced to nearly nothing. Would it then be in my interest to vote? Only if I can be reasonably sure that I know enough to vote in my interest. Karl Marx (1852) thought the French peasants of the mid nineteenth century did not know enough and that they harmed themselves with their votes. US air-traffic controllers might soon have concluded that their voting for Ronald Reagan in the presidential election of 1980 was stupid (he fired them when they went on strike). Some people know enough to judge the relation between elections and their interests accurately. Most people may have too limited knowledge and theory to judge that relation. If they are to vote rationally, therefore, they must acquire information. Typically it is costly to acquire information, and often the costs of relevant information for voting would far outweigh the discounted value to oneself of one's vote.

It is sometimes suggested that we can overcome the logic of Downs' rational voter by imposing sanctions on those who do not register and vote. But this is not a full solution - indeed, it might have perverse effects on elections because it may typically still not be rational for a voter to learn enough to make intelligent decisions. A requirement that people register and vote could be monitored relatively easily and cheaply. A requirement that they be prepared to vote intelligently could probably not be monitored without becoming massively intrusive. Moreover, the collective benefit from having everyone be well informed might be reckoned less than the collective costs of the required study. Hence, it seems reasonable to conclude from the rational-choice theory of citizen

participation in democratic politics that democracy faces severe constraints and that much of philosophical democratic theory is outside the realm of real-world politics (see Democracy §4).

Suppose the logic of the economic theory of democracy is correct and that the assumptions about individual capacities are roughly right. If ought implies can, it follows that most so-called democracies should not be the democracies of the democratic theorists. Hence, a theory that is about possibilities and that is based on simple assumptions of the weights of costs and benefits to individuals and groups yields fundamentally normative conclusions.

Unfortunately for simple, stable visions of democracy, there is a third major result in the economic theory. One of the obvious simplifications of Downs' theory was his assumption of a one-dimensional policy space along which voters are arrayed from left to right. If the world is more complex than this and there are two or more policy dimensions that do not collapse into each other, the results can be chaotic. Slight changes in location of candidates can entail radical changes in election outcomes. If candidates attempt to respond to each other, the winning policy position can be anywhere in the entire policy space. Every outcome is democratic - or none is.

6 The logic of collective action

Suppose we are members of a group who share an interest in having some policy adopted but that every one of us would rather be a free-rider on the efforts of others than contribute toward providing our common benefit. If we all attempt to be free-riders, we will none of us enjoy any collective provision. It is in the group's interest to have the good provided even at its costs; but it is in no individual member's interest to provide any part of the good. The economist Olson has called this the logic of collective action (Olson 1965; Hardin 1982).

It is commonly said that doing something is in *our* interest and therefore in the interest of *each* of us. Indeed, this is the central argument of distressingly many newspaper editorials on such problems as pollution, urban blight, war and peace, and ending poverty. The argument is wrong. Before Olson, the standard theory of groups fallaciously supposed that what was in a group's interest was in the individual group member's interest. In one very influential theory, it was supposed that, in order to predict policy, we need only do a vector sum of the force of all the relevant groups, with each group's vector length given by its number of members and its vector direction given by its policy preference. Hence, if there was a very large group with an interest, there would be policies adopted to satisfy much of the interest. This was a fallacy of composition - perhaps best called a fallacy of decomposition - but it is hard to read the error directly in traditional group theories. Anyone who stated the matter articulately would plausibly have recognized its illogic.

The full panoply of possible groups includes, in Olson's terms, privileged, latent, and intermediate groups. In a privileged group at least one person values provision (of some good that benefits a group) enough to pay fully for its provision - and therefore we might expect provision. In a latent group, every member has the preferences of the free-rider and therefore we expect no provision. In an intermediate group, every member has the preferences of a free-rider but the group is small enough and close enough for interactions that might produce greater cooperativeness and therefore, possibly, provision. In political contexts it is often seemingly true that small, well organized industrial groups can succeed in acting collectively for their political benefit, as in lobbying for privileged legislation or helping the relevant candidate win election. At the same time, the large group of much, even most, of the public is latent and fails to organize well enough to lobby for or against legislation of interest to the group or to support relevant candidates. The rational-choice theory of group behaviour therefore suggests that government outputs will be biased in favour of concentrated interests and against wider public interests.

7 Further applications

The rational choice theory of democracy suggests that we should want to understand the relation of individuals to the institutions in which they have roles and with which they have to deal in social life. If an institution is comprised of individuals in some structure of roles, then we should be able to give an individual-choice theory of institutions. This has long been a major programme, as in the work of Smith, Bentham, and Mill. It is the reputed next project for bringing Rawls' theory of justice to bear in a real world. It is a frequent worry in jurisprudence and in the resurgence of constitutional thinking after the extraordinary events of 1989 in eastern Europe. And it is a major industry in organization theory in economics, psychology, and sociology.

The modern public-choice programme in economics is often attributed to the judgment of Joseph Schumpeter that standard economics applies as well to public as to market choice because it is essentially a theory of the effects of incentives (see Schumpeter, J.A. §3). One could generalize Schumpeter's recommendation that we apply standard economic theory to government as well as the market and recommend that we apply it to all of human behaviour. This would be audacious, perhaps, and possibly misguided. But the recommendation has been taken up by many theorists, who have applied rational choice, game theory, standard price theory, equilibrium analysis, and other devices of economics to family relations, altruism, racism, crime and sex (Becker 1976), to theory of knowledge, norms, and group identification (Hardin 1995), to the rise of states (Levi 1988), to agency, religion, addiction, war, trust, and whatever ails or moves us. Rational choice theorists commonly treat motivation from anything other than interest or personal preference as an anomaly to be explained, not only for actions in the province of public choice but, increasingly, for action across the broad spectrum of life. In return, economics has benefited from feedback from social concerns in the information economics of Stigler and others, theories of cognitive limits associated with Herbert Simon and concerns with fairness and distributive justice.

8 Intentional behaviour

In rational-choice explanations there are commonly generalizations that do not turn on asking every relevant person in a decision-making group why they act as they do. Instead of asking, the rational choice theorist simply assumes a pattern of interests or of costs and benefits. Sometimes, it would be wrong to take people's claims for their actions and motives as compelling. Twentieth-century social and psychological thought has been receptive to the supposition that much of our motivation is not recognized by us. From Freudian psychology to mass movement sociology to economic and rational choice, it is commonly assumed that people act intelligibly but with poor understanding of their own actions.

Much of twentieth-century psychology and, to a lesser degree, other social sciences, was a reaction to this assumption. Since it has often been assumed that we cannot know what is going on in other people's minds many psychologists and others have insisted on considering only behavioural data, not putative mental events. In face of the Freudian vision of mental processes, one can imagine that behaviourism was appealing to many psychologists in the early twentieth century. Behaviourism has sometimes been identified with logical positivism in the philosophy of science, but the identification fails for those who are otherwise positivist but are none the less interested in mental explanations that involve such notions as rationality, instinct, or moral commitment (see Behaviourism in the social sciences; Behaviourism, methodological and scientific).

The social sciences in which behaviourism has had the least impact are economics and anthropology. There may be many reasons for the relative paucity of behaviourist theory in economics. First, and arguably the most important, is that much of economics hardly makes sense as anything but a theory of choice, and much of choice hardly makes sense as anything but mental events. Ideally, a chooser should be able to justify a choice, as must a theorist. In a similar way, rational choice explanations of behaviour cannot be merely behaviourist. They involve attributions of rationality to actors. Second, it may be true that for many problems of interest, economists can safely enough assume that behaviour is fully indicative of preference - typically a mental notion - because some preferences are virtually objective or universal. Much of what is called behavioural economics is about such quasi-objective or universal preferences. For such objects of choice, behaviour is a good proxy for mental preference. Third, economists may often find that attempting to ground theory in strictly behavioural assumptions, as in revealed preference theory, is less fruitful than relying on mental notions.

The grievous problem for explanations based on the mental notion of rationality is that, if the theory is worth doing, the explanations go beyond what the actors themselves understand of their actions. For example, when Olson presented his logic of collective action, when Flood and Dresher presented the game that is now known as the prisoner's dilemma, when Hume and, much later, David Lewis presented their theory of coordination, and when economists argue for rational expectations, they all go beyond what the subjects of their theories have recognized. If all these things had already been understood by the actors, there would be little point of doing social science, which would lead not to discoveries but merely to catalogues. Yet it seems absurd to say that people who cannot or who have never yet had occasion to understand these theories are not acting according to them. Indeed, the astonishing thing about these and many other theories is that they make sense of commonplace behaviour in *de facto* mental terms - for example, by showing that the behaviour is rational.

9 Value theory

There are several problems at the foundations of rational choice. In addition to the problem of indeterminacy discussed above (§§3-4), there are problems in the underlying value theory. I will discuss only two categories of these: variant rationality assumptions and the relations between interests, consumptions, and utility.

First consider variant rationality assumptions. When game theory first appeared it was praised as brilliant but damned as irrelevant by economists in the vanguard of the ordinal revolution. They held two counts against the von Neumann-Morgenstern utility theory. It was interpersonally comparable and it was cardinal. Decades earlier, Pareto had argued forcefully against interpersonal comparability and most economists agreed with him in principle (although they also regularly did cost-benefit analyses that violated Pareto's view). With cardinality, payoffs could be added or combined in probabilistic functions. As discussed above (§4), cardinality violated evident sense - and, perhaps worse, it was unnecessary for economic theory.

Immediately, von Neumann responded to economist critics with his proof that anyone with complete ordinal preferences, including preferences over probabilistic combinations of outcomes, has preferences that are cardinal up to a linear transformation. This claim mirrors an earlier claim by the philosopher Frank Ramsey (1931). Around this view there has risen a vast body of theory about individual decision making under uncertainty and the Bayesian theory of decision. Even a rejected value theory seems to bear fruit. Still, the ordinalists may note that Bayesian or von Neumann value theory is seemingly restricted to contexts in which there are no major effects of substitutability and complementarity among the elements of an outcome.

In the longer run, game theory and the utility theory of von Neumann and Morgenstern were seen as separable, and ordinal games are widely used. For much of game theory even in the original tradition, the use of cardinal, interpersonally additive preferences may often be little more than a mathematical crutch to ease the way to a solution.

Now turn to interests, consumptions and utility. Satisfying interests enables consumptions, which produce or have utility. Interest is therefore merely proxy for the utility of eventual consumption. If we include all consumptions now and into the future in our choice function, as in Arrow's fully determined states of affairs, interest drops out. Note that interests and consumptions trade off against each other. It is against my interest to consume an opera tonight; but if I could not do such things, I would have little interest in living. It is the very point of my interest in various resources that they enable me to consume and enjoy.

To do rational choice theory with interests instead of the full complexity of consumptions superficially might seem to simplify the account. But the costs of consumptions need not be linearly related to their utility or the enjoyment of them. Using interests as a proxy for consumptions is therefore potentially misleading, although it might often be relatively sensible. The cardinal value theory of von Neumann and Thomas Bayes might apply to simply conceived interests but not so readily to a panoply of consumptions. To put this the other way around, focusing on interests allows us to think cardinally; focusing on consumptions virtually forces us to think ordinally.

10 Preliminary conclusions

Two conclusions from the rational choice theory and one conclusion about it seem evident. The first two of these are the grievous problem of indeterminacy and the difficulties of democratic theory. Indeterminacy seems to inhere in the problems we face: aggregation from individual to social choice. It is a large part of the cause of difficulty for democratic theory. If certain choice procedures were not indeterminate, we could plausibly reach strong conclusions about the relation of democratic procedures to best outcomes. But if the category of 'best outcomes' is conceptually empty or meaningless, we may have no ground from which to judge particular procedures.

The third conclusion is that rational choice theory has been remarkably successful in the sense of systematically addressing and, in its own terms, resolving an enormous number and variety of issues. This success poses an interesting question in the philosophy of the social sciences. Why has rational choice theory been so successful? A first answer might be that it is like utilitarianism and economics - it has a programmatic approach that is broadly applicable and it has a highly refined value theory. Or rather it has several highly refined value theories, each developed over centuries by many of the best social theorists. Even in the central disagreement over the relevance of ordinal and cardinal utility theories, there is programmatic and sustained focusing of the issues.

A second answer might look instead to the standard against which the theory seems to be successful: the relative success of other approaches to social theory. Social theory often seems to be faddish - we go from one perspective to another. In many other branches of knowledge there may also be fads, but these seem to be about marginal matters while the core continues. A summary account of twentieth-century social theory would be dizzying in its rollicking from one fad to another. Many of these have gone to the core of one or more of the social sciences. A striking feature of many of the faddish movements is that they are critical, they are not constructive. Once its criticism is adequately made, each critical theory goes into decline. If rational choice theory is to go into decline, it will not be from exhaustion but from failure, which can probably happen only if a more successful approach is invented. Rational choice theory has had the advantage of centuries of coherent development that cannot soon be matched by a new approach.

Rationalism

Rationalism is the view that reason, as opposed to, say, sense experience, divine revelation or reliance on institutional authority, plays a dominant role in our attempt to gain knowledge. Different forms of rationalism are distinguished by different conceptions of reason and its role as a source of knowledge, by different descriptions of the alternatives to which reason is opposed, by different accounts of the nature of knowledge, and by different choices of the subject matter, for example, ethics, physics, mathematics, metaphysics, relative to which reason is viewed as the major source of knowledge. The common application of the term 'rationalist' can say very little about what two philosophers have in common.

Suppose we mean by reason our intellectual abilities in general, including sense experience. To employ reason is to use our individual intellectual abilities to seek evidence for and against potential beliefs. To fail to employ reason is to form beliefs on the basis of such non-rational processes as blind faith, guessing or unthinking obedience to institutional authority. Suppose too that we conceive of knowledge as true, warranted belief, where warrant requires that a belief be beyond a reasonable doubt though not beyond the slightest doubt. Here, then, is a version of rationalism: reason is the major source of knowledge in the rational sciences. This is a weak version of rationalism which simply asserts that our individual intellectual abilities, as opposed to blind faith and so on, are the major source of knowledge in the natural sciences. It is clearly not very controversial and is widely accepted.

Suppose, however, we take reason to be a distinct faculty of knowledge distinguished from sense experience in particular. To employ reason is to grasp self-evident truths or to deduce additional conclusions from them. Suppose we conceive of knowledge as true, warranted belief, where warrant now requires that a belief be beyond even the slightest doubt. Let us also extend our attention to metaphysics and issues such as the existence of God, human free will and immortality. Here is a much stronger version of rationalism which asserts that the intellectual grasp of self-evident truths and the deduction of ones that are not self-evident is the major source of true beliefs warranted beyond even the slightest doubt in the natural sciences and metaphysics. Clearly it is highly controversial and not very widely accepted.

The term 'rationalism' has been used to cover a range of views. Scholars of the Enlightenment generally have in mind something like the first example - a general confidence in the powers of the human intellect, in opposition to faith and blind acceptance of institutional authority, as a source of knowledge - when they refer to the rationalist spirit of the period and the work of such philosophers as Voltaire. Most frequently, the term 'rationalism' is used to refer to views, like the second one above, which introduce reason as a distinct faculty of knowledge in contrast to sense experience. Rationalism is then opposed to empiricism, the view that sense experience provides the primary basis for knowledge. This entry concentrates on this still very general form of rationalism, reserving the term 'rationalism' for it alone.

1 Continental Rationalism and British Empiricism

The rationalist-empiricist division has traditionally played a major role in our understanding of the history of philosophy, particularly that of the modern period of the seventeenth and eighteenth centuries leading up to Kant. The major philosophers of the period are regularly grouped into two sets of three: Descartes, Spinoza and Leibniz are the Continental Rationalists, in opposition to Locke, Berkeley and Hume, the British Empiricists. Philosophy department curricula, textbooks, scholarly anthologies and conference programmes have all incorporated the classification for years and are likely to continue to do so.

None the less, scholars have at least five basic reservations about its accuracy. First, a close study of the three Continental Rationalists, especially their work in the natural sciences, reveals they had a great respect for the role played by experience in scientific knowledge. Second, the British Empiricists, especially Locke and Berkeley, stress, in one way or another, the importance of reason as a source of knowledge; consider Locke's account of a priori knowledge and Berkeley's acceptance of innate ideas. Third, the division encourages us to overlook important areas of agreement between philosophers on different sides of the divide, such as the views of Descartes and Locke on the nature, though not the source, of our ideas. Fourth, the division encourages us to associate irrelevant differences in language and geography - those who do not write in English against those who do; the Continent against England and Scotland - with a supposed difference in philosophical views. Fifth, the grouping of

the six philosophers in epistemological terms encourages an incorrect grouping of them in metaphysical ones. The Continental Rationalists are mistakenly seen as attempting to apply their reason-centred epistemology to pursue a common metaphysical programme, each trying to improve on the efforts of those before him; the British Empiricists are incorrectly seen as gradually rejecting those metaphysical claims, with each again consciously trying to improve on the efforts of predecessors. Defenders of the Continental Rationalists-British Empiricists distinction generally admit many, if not all, of these shortcomings but treat them as minor anomalies.

This entry does not attempt to resolve the controversy or even to lay out each side's supporting evidence from the works of the philosophers involved. A few points deserve mention, however. First, in evaluating whether it is appropriate to classify these philosophers in this way, we must consider what purpose the classification is supposed to serve. The classification might well be acceptable for pedagogical purposes at a certain level of instruction in the history of philosophy in order to initiate consideration of their views, but not at another level or for other purposes.

Second, attempts to group philosophers into such families as the rationalists and the empiricists are best understood as attempts to classify them by shared family resemblances. The question to ask, then, is not whether there is a list of interesting claims the acceptance of which is definitive of being a Continental Rationalist and the rejection of which is definitive of being a British Empiricist, so that Descartes, Spinoza and Leibniz may each be classified as a Continental Rationalist just so long as all those claims are accepted, and Locke, Berkeley and Hume may each be classified as a British Empiricist just so long as one rejects them. Critics of the classification sometimes present the issue in this way but few, if any, proponents see it in these terms. We need to consider whether there is an interesting list of claims emphasizing reason as a source of knowledge of the external world, a sufficiently large number of which are accepted by each of Descartes, Spinoza and Leibniz and rejected by each of Locke, Berkeley and Hume, though the first three may not accept all the same claims and the second three may not reject all the same ones.

Third, independently of the historical accuracy of the classification, the terms 'rationalist' and 'empiricist' are associated with some basic claims which define the family resemblance for each category. The rest of this entry focuses on the innate idea thesis and the demonstrative knowledge thesis. Minimal attention will be given to the sometimes complex scholarly questions of whether and why the claims are actually adopted by Descartes, Spinoza and Leibniz, and rejected by Locke, Berkeley and Hume, though some of these philosophers will be cited as examples where the attribution is fairly uncontroversial.

2 Innate ideas

To gain knowledge about the external world we need to think about it and thus we need the appropriate concepts. How do we gain them? One of the central theses associated with rationalism is that at least some of our concepts are not gained from experience but are instead innate. Descartes, for example, divided our ideas into three categories: adventitious ideas, such as our idea of red, are gained through sense experience; fictitious ideas, such as our idea of a hippogriff, are manufactured by us from other ideas we possess; innate ideas, such as our idea of God, of extended matter and of a perfect triangle, are placed in our minds by God at creation.

It is important to distinguish the innate-idea thesis from some other ones. The term 'innate' is often associated with things other than concepts. Some rationalists, for example Descartes and Leibniz, write of innate propositions as well as innate concepts. They seem to have in mind that we have beliefs, in particular true propositions, as part of our initial mental make-up rather than as a result of experience; the propositions are presumably constructed of innate concepts. Whether and just how such true beliefs might constitute knowledge is not clear. Some philosophers have also claimed that we have innate knowledge, though it is not always clear whether this is 'knowing that' or 'knowing how' (see Innate knowledge; Nativism). It has been maintained by contemporary philosophers, for example, that learning a natural language requires a knowledge of grammar which is 'innate' in that learners could not have inferred it from their experience. The focus in this section is solely on the thesis that some of our concepts are innate (see Concepts). The central rationalist positions on knowledge are considered in the next.

Some defences of the innate idea thesis are based in claims peculiar to particular philosophers. Leibniz's view that all substances are causally isolated monads implies a general rejection of sense experience as a source of any ideas

and so supports the claim that all ideas are innate. (‘It is a bad habit we have of thinking as though our minds receive certain messengers, as it were, or as if they had doors or windows. We have in our minds all those forms for all periods of time because the mind at every moment expresses all its future thoughts and already thinks confusedly of all that of which it will ever think distinctly,’ Leibniz 1685: Section 26.) The most common defence of the innate-idea thesis, however, takes the form of admitting experience as a source of ideas but then arguing that some concepts could not have been gained directly or indirectly from experience; that these concepts are innate is then offered as the best explanation of their existence. That the concepts could not have been gained from experience is generally defended in one or both of two ways. First, the content of the concepts is beyond what we directly gain in experience as well as anything we could gain by performing the available mental operations on what experience provides. Second, our possession of the concepts is presupposed by our ability to employ the very empirical concepts that might be thought to provide a basis for them in experience.

Consider, for example, Descartes’ defence of the claim that our concept of God, as an infinitely perfect being, is innate. This concept is not directly gained in experience, as a particular sensation of pain might be. Its content is far beyond any we could ever construct by applying available mental operations to what experience provides. Our empirical concepts include the concept of a finitely knowledgeable, powerful and good being; we can even construct the concept of a finitely but *very* knowledgeable, powerful and good being, but we cannot move on to the concept of an infinite one. We cannot, for example, gain the idea of infinite perfection by simply negating our concept of finite perfection. (‘I must not think that, just as my conceptions of rest and darkness are arrived at by negating movement and light, so my perception of the infinite is arrived at not by means of a true idea but merely by negating the finite’ (Descartes 1641: Third Meditation).)Moreover, we must possess the concept of infinite perfection in order to employ the concept of finite perfection gained from experience. (‘For how could I understand that… I was not wholly perfect, unless there were in me some idea of a more perfect being which enabled me to recognize my own defects by comparison’ (Descartes 1641: Third Meditation).)

Objections to the standard arguments for the innate-idea thesis generally take two forms. The less radical line of objection, exemplified by Locke, is to argue that the supposedly innate concepts are indeed gained by sense experience and to offer an account of the mental processes involved. The more radical critique, exemplified by Hume, is to agree that the supposedly innate concept could not be gained by experience and to argue that we do not in fact have the concept as understood by the innate-idea theorists in the first place; a failure to find an experiential source for a supposed concept should not lead to us to the innate idea thesis but to a critical examination of our concepts themselves (see Locke, J. §2; Hume, D. §2).

Besides defending their theory, innate-idea theorists face the task of explaining exactly what it is for an idea to be innate. Innate concepts are in the mind from creation but are not present in consciousness until we actually conceive them. How are these concepts ‘in the mind’ prior to being present to consciousness? How too can any of them, prior to being present to consciousness, serve as a precondition of our employing other ideas gained from experience?

Finally, innate idea theorists often assume that the ways in which we conceive of the external world using our innate concepts actually correspond to how it is, and they thus face the question of what justification, if any, there can be for this assumption. A frequent strategy is to find a non-deceptive source for our innate concepts - be it a non-deceiving God, as for Descartes, or a non-sensory experience by the soul prior to its union with the body, as in Plato’s doctrine of recollection (see Plato §§11-14).

3 Intuition and demonstration

A second thesis generally identified with rationalism is the claim that reason alone can provide us with at least some knowledge of the external world through our intuition of self-evident propositions and our subsequent deduction of additional information from those starting points. Intuition is understood as a kind of intellectual ‘grasping’ by which we comprehend a proposition in such a way as to recognize its truth; in a demonstration we reason through a series of intuited premises to a logically entailed conclusion. Propositions known by intuition are self-evident, while those known by demonstration are evidenced by the intuited premises; in either case the knowledge is a priori, independent of evidence gained from sense experience (see A priori).

It is essential to the rationalist account of knowledge by intuition and demonstration that the knowledge gained in

this way is knowledge of the external world. Many empiricists, indeed even Hume, are willing to admit that an intellectual grasping of our concepts can provide us with a priori knowledge, but they limit that knowledge to knowledge of the relations of our ideas: when we intuit that two plus three make five, we gain knowledge about how the concepts involved are related, but we do not learn anything about the world as it exists independently of our mind.

The rationalist commitment to intuitive and demonstrative knowledge of the external world is not necessarily a commitment to have such knowledge of propositions affirming the existence of particular concrete objects. It may take the form of a commitment to have such knowledge of abstract objects which none the less exist, and are as they are, independently of our thought. Descartes, for example, claimed that while he had no knowledge of the existence of any particular triangle, he none the less had an intuitive and demonstrative knowledge of propositions about the properties of a triangle and that the content of his knowledge was a 'determinate nature' independent of his mind.

The rationalist account of knowledge under consideration involves a version of foundationalism. It endorses the view that we know some propositions independently of their being evidenced for us by any other propositions; these basic propositions provide us with the evidential base for additional knowledge (see Foundationalism). Rationalists generally adopt a strong view about the strength of our intuitive and demonstrative knowledge. When we intuit a proposition we know it to be true with certainty. Our intuitive grasp places it beyond even the slightest doubt. This extreme degree of epistemic justification can only be transferred to other beliefs by deductive inference which precludes the possibility of the conclusion being false while the premise is true. Even our ability to gain additional knowledge by demonstration is limited. Once our demonstrations get so lengthy as to rely on memory, the possibility of a mistake in recall weakens our degree of justification. (On some interpretations of Descartes' epistemology, a major aim of his epistemic programme is to remove the limitation that this reliance on memory placed on the certainty of our demonstrations.)

Rationalism is sometimes identified with the view that every science has the same deductive structure in which knowledge moves from the intuition of self-evident axioms to the demonstration of theorems. It is thus seen as endorsing a single method for all sciences and as asserting the priority of the knower over the known: as we move from one subject to another - from mathematics to physics - the subject matter changes, but so long as the nature of the knower's mind remains constant the same method of intuition and demonstration may be used in each case. The Continental Rationalists were all impressed by the rigour and certainty associated with the deductive method of mathematics and they stressed the importance of meeting such standards in other areas. So too, Descartes and Leibniz, like Galileo, were quite concerned with the application of mathematics to the natural sciences. Yet, it is clearly a mistake to attribute to them individually, or to rationalism generally, the view that all science proceeds by intuition and demonstration. Even though Descartes, for example, attempted to use intuition and demonstration to establish some basic laws of nature (that whatever is in motion continues in motion in so far as it can, that all motion is rectilinear, and so on), he admitted that we need to use experiments to move beyond very basic principles.

Just as the innate idea thesis is partially motivated by the belief that sense experience can not provide some concepts we clearly have, so too the rationalist belief in knowledge of the external world by intuition and demonstration is often at least partly motivated by the conviction that sense experience falls short of providing us with knowledge in some areas. Our claims in mathematics, metaphysics and ethics, for example, seem to outstrip the content of our sense experiences. We experience lots of imperfect triangles but no perfect ones, we may experience the effects of God's creative powers but not God, and we experience how things are but not how they ought to be. So how can we have knowledge in such areas? Intuition and demonstration provide an alternative account; one that becomes increasingly attractive when the other main option seems to be scepticism (see Scepticism).

The rationalist appeal to intuition and deduction is also at times motivated by a demanding conception of knowledge that seems to require more than experience can provide. Descartes' conception of knowledge as permanent supported his requirement that it be absolutely certain which in turn placed it beyond sense experience. Whenever we form beliefs on the basis of sense experience, the possibility that our senses are deceiving us keeps us from absolute certainty (see Certainty; Doubt; Fallibilism). Here again, intuition and demonstration provide an

attractive alternative, especially given their apparently successful use in mathematics with its high degree of epistemic justification.

4 Intuition and demonstration (cont.)

Some of the difficulties for the rationalist appeal to intuition and deduction arise out of the reasons for rejecting sense experience. If knowledge requires certainty, what makes our intuitions and subsequent demonstrations certain? We have already noted the worry about the use of memory in extended demonstrations (see Memory, epistemology of). What makes our intuitions a source of certainty even while we are having them? Could not a deceitful God have us intuit false propositions, just as easily as we might deceive ourselves in a dream? Do not such epistemic possibilities as a deceitful God give us at least a slight reason to doubt our intuition that two plus three make five, preventing it from being absolutely certain?

One rationalist strategy for responding to this difficulty is to offer an argument for the veridicality of our intuitions. Once we establish that our intuitions are non-deceptive, we can gain certainty by them, and we can establish the universal veridicality of our intuitions while we cannot establish the universal veridicality of our sense experiences. Yet, the argument for the truth of our intuitions will only meet the sceptical challenge if it establishes its conclusion with certainty, and the demand for certainty thus requires the rationalists to rely on intuition to support the premises of their argument for the veridicality of intuition. They thus fall into an apparently vicious form of circular reasoning (sometimes called the ‘Cartesian Circle’ in recognition of Descartes’ struggle with the problem). A second strategy is to claim that all our intuitions are certain, even when we have not gained certain knowledge that the faculty never deceives. Whenever we intuit a proposition, we are certain of it; such hypotheses as that of a deceiving God do not give us a reason to doubt it, even if they are epistemic possibilities for us. This strategy risks being *ad hoc*: why should we accept intuition as an automatic source of certainty?

Appeals to intuition carry a related methodological problem. Let us assume that real intuitions are always true and always certain. How do we distinguish between real intuitions and only apparent ones, and how do we get ourselves in a position to have the former but not the latter? People have taken themselves to ‘just see’ the truth of all sorts of contradictory claims; they cannot all be correct (see Pyrrhonism). Descartes’ method of doubt is intended to help us gain a psychological state where we will have real intuitions, but his own extravagant list of ‘intuited’ propositions in the course of following his method illustrates its ineffectiveness.

Another difficulty for the rationalist reliance on intuition and demonstration takes us back to the view that some claims about the external world fall beyond the range of our sense experience but within that of intuition and demonstration. The rationalist must argue that the contents of intellectual intuition are independent of us in such a way that, as in Descartes’ theory of simple natures, our knowledge of how they are related is not just knowledge about the structure of our own thoughts. Rationalism, while primarily an epistemological position, thus involves its proponents in at least some metaphysical commitments (see Introspection, epistemology of).

According to many contemporary epistemologists, rationalism, like such related theories as foundationalism, is dead. It surely is beset with problems in both the innate idea thesis and the demonstrative knowledge thesis. Yet, a complete evaluation of rationalism must involve more than an examination of these two central points. It must also include an overall examination of the nature and extent of our knowledge and the nature and extent of our experience. Rationalism, in one form or another, will remain attractive so long as we find that we have knowledge of the external world which appears to go beyond what experience can provide.

Rationality and cultural relativism

Under what conditions may we judge the practices or beliefs of another culture to be rationally deficient? Is it possible that cultures can differ so radically as to embody different and even incommensurable modes of reasoning? Are norms of rationality culturally relative, or are there culture-independent norms of rationality that can be used to judge the beliefs and practices of all human cultures?

In order to be in a position to make judgments about the rationality of another culture, we must first understand it. Understanding a very different culture itself raises philosophical difficulties. How do we acquire the initial translation of the language of the culture? Can we use our categories to understand the social practices of another culture, for instance, our categories of science, magic and religion? Or would the mapping of our categories on to the practices of culturally distant societies yield a distorted picture of how they construct social practices and institutions?

A lively debate has revolved around these questions. Part of the debate involves clarifying the difficult concepts of rationality and relativism. What sort of judgments of rationality are appropriate? Judgments about how agents' reasons relate to their actions? Judgments about how well agents' actions and social practices conform to the norms of their culture? Or judgments about the norms of rationality of cultures as such? Can relativism be given a coherent formulation that preserves the apparent disagreements for which it is meant to account?

Can there be incommensurable cultures, such that one culture could not understand the other? According to Donald Davidson's theory of interpretation, radical translation requires the use of a principle of charity that in effect rules out the possibility of incommensurable cultures. If this result is accepted, then a strong form of cultural relativism concerning norms of rationality is also ruled out.

Davidson's theory, some argue, does not eliminate the possibility of attributing irrational beliefs and practices to agents in other cultures, and thus still leaves some room for debate about how to understand and evaluate such beliefs and practices. Three positions frame the debate. The intellectualist position holds that judgments of rationality are in order across cultures. The symbolist and functionalist positions, here taken together, try to avoid such judgments by attributing functions or symbolic meanings to cultural practices that are generally not understood as such by the agents. The fideist position, wary of too easily being ethnocentric, assumes a more relativist stance with regard to cross-cultural judgments of rationality.

1 Background to the debate

Interest in questions of cross-cultural understanding and judgment can be found among the Greeks, in Herodotus for instance. At the beginning of the modern period, Giambattista Vico in *The New Science* (1744) in effect raised many of these issues in his attempt to develop a new science of human history (see Vico, G. §§4-6). The modern preoccupation with these questions, however, began only with the development of anthropology in the late nineteenth century. Evidence began to accumulate of apparently irrational beliefs and associated practices in diverse cultures. How was this evidence to be assessed and explained? The founders of anthropology, including Sir Edward Tylor, Sir James Frazer, Bronislaw Malinowski and Lucien Levy-Bruhl, reacting to the encounter between European and non-European civilizations and noting the diversity of cultural practices and beliefs, debated these issues largely in terms of the now suspect categories of 'civilized' versus 'savage' or 'primitive' societies, or of 'pre-logical' and 'pre-scientific' versus 'logical' and 'scientific' cultures. While largely rejecting this terminology, a later generation of philosophers and anthropologists carried on a debate about essentially the same issues, with a particularly intense period of discussion occurring in the 1960s, 1970s and into the 1980s. Some argued that the best account of the apparent irrationalities found in other cultures was in terms of a theory of cultural relativism. Others rejected relativism of any sort (see Anthropology, philosophy of §1). Rather than reaching a resolution, the debate about rationality and cultural relativism continues and draws closer to parallel debates in the history and philosophy of science and epistemology generally.

The participants in this debate use a number of difficult concepts and not always in the same way. Clarification of the concepts of rationality and relativism is required before the various positions in the debate can be presented.

2 Rationality

A wide variety of things can be said to be rational or irrational. In the context of the debate about the rationality of distant cultures, the most important are beliefs, individual actions and cultural practices. Rationality, in general, has to do with how people acquire beliefs from evidence and connect reasons to actions. At the most basic level, rationality concerns the standards for truth, consistency and deductive and inductive inference. The concept of rationality is standardly used in a normative sense, that is, one that conveys commendation or endorsement. To call an action rational is to certify that there is good reason to do the action or to judge that the action was brought about in a suitably correct way. Likewise, to describe an action as irrational is to indicate that there is not good reason to do the action or to judge that there was some error or fault in how the action came about and to criticize it (or rather, the agent performing the action) in that regard (see Rationality of belief; Practical reason and ethics; Reasons for belief).

Focusing on the rationality of action, we can usefully distinguish three levels where judgments of rationality may be made. The first level regards individual actions. According to the model of rational action suggested by Davidson, a rational action is one that stands in a certain relation to the agent's beliefs and desires, that is, their reasons for acting. For example, if a person has a desire, all things considered, to bring about goal X, and believes, all things considered, that action A is the most effective means to goal X, then the person acts rationally if they bring about action A for those reasons. This formulation simplifies things considerably. In some instances, it may be rational to choose an action that is suitably effective, but not the most effective one. Thus, there may be more than one action that would be rational, given an agent's reasons. In this case, the concept of rationality would limit but not uniquely determine the action to be chosen.

On this level, an agent would be acting irrationally if they did not choose the action that was the most effective (or at least a suitably effective) means to goal X; that is, if the agent's reasons were not good reasons for the action chosen. This failure might occur for a number of complicated reasons, most of which involve some sort of failure of critical thinking or consistency. While capturing the standard notion of instrumental rationality, this model, in this context, is meant to apply to more than what might be thought of as narrowly instrumental action. Thus, actions oriented towards successful communication or successful participation in a ritual can be understood in terms of the model with suitably adjusted notions of effective means towards those goals.

The second level where judgments of rational action may be appropriate involves questions about the agent's reasons (beliefs and desires), in particular, questions about how the agent acquired the reasons. Is the belief appropriately related to the available evidence? Does the evidence come from a reliable source? Is the evidence reliable such that the agent has good reasons for the action undertaken?

One way to understand what makes the relationships of evidence to beliefs and of reasons to action good or appropriate is to ask: (1) whether a belief was acquired by an agent in a way that conformed to the epistemic norms of the agent's culture, and (2) whether the agent's reasons (beliefs and desires) provide good reasons for the action according to the canons of reasoning of the agent's culture. Putting the questions in this way allows space for what seems to be a form of cultural relativism. If different cultures have different and conflicting epistemic norms and/or canons of reasoning, then a belief might be rationally acquired according to the norms of one culture but not according to those of another, or provide good reasons for an action in one culture but not in another. For instance, if a certain way of reading omens is considered a reliable means of evidence gathering in one culture but not in another, then reading omens to acquire evidence for beliefs and acting on those beliefs would be considered rational by the standards of the first but not the second culture. Likewise, inductive counter-evidence might be assigned different weight in different cultures, affecting what is considered a good reason for action. Thus, at this level, judgments of the rationality or irrationality of an agent's action can be regarded as intersubjective judgments relative to the norms of the agent's culture.

The move from the second level, thus construed, to the third is readily apparent. Can one make judgments of the rationality or irrationality of the norms of a culture? If we can make such judgments, then the action of an agent might on analysis turn out to be rational on the first two levels but still be irrational from the point of view of the third. For instance, if omen reading is judged not to be epistemically rational, then omen reading, and actions based on omen reading, could still be judged irrational even if they took place in a culture that endorsed the practice. (It should be noted that an action that was judged irrational on the second level because it was not properly related to the norms of the agent's culture in a way that the culture would regard as rational, might still

turn out to be rational on the third level if the agent's individual norms were judged rational.)

Given this analysis of rationality, we can restate some of the questions central to the debate. From what point of view might we make such third level judgments of the rationality or irrationality of a culture's norms? Is the only available position that of the norms of rationality of our culture? If so, should we restrict ourselves to second level judgments only? If we make third level judgments, are we really judging the other culture to be irrational, or only different? And what would we mean by such a judgment of cultural irrationality? What sort of mistake would a culture so judged be making?

3 Relativism

Relativism is a notoriously difficult concept. The form of relativism of primary concern here is cultural relativism with regard to norms of rationality. What such a relativist theory typically holds is that (1) norms of rationality differ across cultures; that (2) judgments of the rationality of a given action are relative to the governing norms of the local particular culture; such that (3) two people, depending on their cultural locations, might disagree about the rationality of the same action, one judging it to be rational and the other irrational, and both judgments would be equally correct.

One implication of this form of cultural relativism is that it denies the existence of a universal or 'objective' system of rationality that could be used to judge the rationality of actions in all cultures. In the terms used above, relativism denies that there is a culture-independent position from which to make third level judgments about the rationality of a culture's norms. The most we can say is that an action seems irrational to us, by the norms of our culture, even while recognizing that by the norms of the culture in which is occurs, the action may be rational.

There is an ongoing debate about whether relativism can be stated coherently in a way that saves the phenomenon for which it is meant to account. The relativist, at least in certain versions of the position, seems to want to endorse as correct propositions that are apparently logically incompatible. On the other hand, where claims are clearly relativized to particular theories or cultures, thus eliminating the appearance of logical inconsistency, it is not clear that genuine disagreement remains. Some maintain that if disagreement is resolved by relativizing apparently competing claims, then part of the phenomenon that relativism is meant to analyse is dissolved rather than accounted for. Also, part of the point of making normative judgments, especially critical ones, is often to offer people reasons for changing their behaviour. If judgments of rationality were thoroughly relativized to particular cultures, however, one could no longer recommend reasons in this way. The critical judgment would seemingly be simply out of place.

Despite the problems that some see with relativism, the position has enough intuitive appeal to have some purchase on us. In matters of taste, for instance, we seem ready to concede that two cultures could have very different standards such that one culture could judge an object beautiful, the other judge it ugly, and the best analysis be that each judgment is correct according to the standards of that culture. It is this sort of analysis that raises the problem of relativism concerning judgments of rationality across cultures.

4 Interpretation and translation

In order to make judgments of the rationality or irrationality of actions in other cultures, one must first understand the actions involved. If one is dealing with distant cultures where the native language is poorly understood or even not understood at all, problems of understanding are obvious, although the same problems occur much closer to home.

Could there be a culture so distant from ours, using norms of rationality so different from ours, that we could not successfully interpret it? In such a case, our culture and the other culture could be said to be incommensurable.

Davidson (1984), building on Quine's work on the radical indeterminacy of translation, argues that there could not be incommensurable human cultures (see Radical translation and radical interpretation). When confronted with the task of translating the language, hitherto unknown, of another culture, we should, counsels Davidson, proceed according to a principle of charity such that most of the beliefs of the people whose language is being translated come out true (see Charity, principle of §4). This would require, among other things, that the speakers of the translated language reason at least roughly as we do.

Some have argued that Davidson’s theory of radical translation leads to what may be called a problem of the attribution of irrationality, for it might seem that according to the principle of charity, it is improper to attribute any appreciable irrationality to those whose language is being translated. When faced with what seem provisionally to be irrational beliefs and practices, one should question the validity of the translation. If this is what Davidson’s theory implies, then it is ruling out irrationality in effect on purely conceptual grounds. This result would seem unduly strong to many, especially in light of the accumulated evidence from social anthropology. Others, however, feel that this interpretation of Davidson is itself uncharitable and that Davidson does not mean to deny the possibility of translating beliefs that may seem irrational to us.

We can assume for present purposes that the principle of charity might be amended into what is sometimes called the principle of humanity. The directive of the principle of humanity is to attempt to make the beliefs and practices of those translated intelligible rather than true. In certain circumstances at least, irrational beliefs could be intelligible, if within the context we could understand how the speakers could acquire them, but still not true. Practices informed by intelligible but false beliefs would thus be intelligible in light of the beliefs. Accordingly, Davidson’s approach thus understood would not rule out the attribution of some kinds of irrationality to those being translated. However, it would rule out translating a language of another culture as involving a radically different system of rationality, that is, different standards of truth and deductive and inductive inference. Attributing to a culture different standards on this basic level would make many of their beliefs and practices appear massively irrational to us, and such massive irrationality could no longer be made intelligible. Thus a strong form of cultural relativism would not be countenanced by a Davidsonian.

5 The debate and its errors

The debate over rationality and cultural relativism has focused on several related questions. The first asks whether we should apply the categories we (in the West) use to divide up cultural practices (for example, science, magic, or religion) to other, significantly different cultures? Do our categories enhance or distort our understanding of others? This question raises the subsidiary question of what has been called the pragmatics of belief: What are people using certain beliefs to do? Are they using the beliefs to explain part of the world, or are they using them to express participation in some aspect of their social reality or religious rituals, or something else again? The other question central to the debate asks when, if at all, and from what standpoint, can we judge the rationality of the beliefs, actions and practices in other cultures?

A variety of positions have been taken in answer to these questions. Before turning to the positions, however, we should note three especially contentious moves that often divide the field. The first is what many would consider a form of ethnocentrism; it holds in effect that our (Western) norms are objectively correct and may be used to assess the rationality of any and all cultures. Many find this position to be culturally insensitive and lacking sound epistemological grounding.

A second view that many reject as inadequate is the opposite of ethnocentrism, namely, a strong relativism. Apart from the various logical and epistemological problems of which relativism is accused, this view appears to many to paralyse judgment, preventing us from making the kinds of judgments about the rationality or irrationality of other cultures that seem intuitively in place.

The third contentious move in effect severs the link between agents’ reasons and actions by explaining the action in terms not immediately available to the agents. This is done in an effort to avoid making others seem manifestly irrational. For many, however, this move merely displaces the problem by reducing away the rationality of other cultures.

6 The intellectualist position

Horton classified the main positions in the debate in a way that will be largely adopted here. The first position is the intellectualist. Among the participants in the early phases of the debate, this position can be associated with Tylor and Frazer. Although their views differed somewhat, Tylor and Frazer sought to explain apparently irrational beliefs in terms of their purpose. For both, the general purpose of belief systems, as they understood them, is to explain, predict and control the world. On this view, systems of beliefs informing practices such as magic, witchcraft and primitive religion are seen as primitive theories, similar to Western science but for the most

part inferior to it, proto-sciences one might say.

Horton (1993) has developed the most sophisticated rendering of the neo-intellectualist position. In his analysis of traditional West African belief systems, Horton finds norms of reasoning and attempts at theory building that are similar to those at work in Western science. African systems often display considerable sophistication and explanatory prowess. Still, for the most part, their explanations are not as successful as those of our sciences. However, in certain instances, Horton notes, African systems provide arguably superior accounts of some phenomena.

By and large, the intellectualist position imports our categories such as science and magic and puts them to work in analysing other cultures. In addition, the position allows for cross-cultural judgments of rationality. Thus, in instances where the norms of a culture appear to countenance the seeming disregard of relevant evidence, or where certain inductive inferences are not drawn upon, for example, the non-efficacy of a rain dance, we can make the third level judgment that the norms are rationally deficient compared to our own.

The intellectualist takes the belief and desire statements of the members of other cultures literally as translated. The beliefs and desires are then construed as the agents’ reasons for action and a corresponding attempt is made to understand how the agents act in their cultural context. Beliefs that, when translated, appear wrong or irrational are judged false and seen as perhaps acquired in an irrational way.

7 The functionalist and symbolist positions

The second position to be examined does not approach the problem in this way. According to this position, beliefs that appear initially to be false or irrational or that appear not to offer good reasons for the associated action are not subject to rational evaluation. Rather, an alternative interpretation is offered that makes the actions rational, even if it means decoupling the actions from the reasons for it offered by the agents. Actions or practices are understood as rational in terms of their function, according to one alternative of this position, or in terms of their symbolic meaning, according to the other. Beliefs are either not considered as part of the explanation of the action or practice, or taken as expressive but not descriptive, as having a predominantly symbolic meaning. In either case, beliefs are not subject to assessment in terms of their literal meaning.

The two variants of this position, the functionalist and the symbolist, should not be entirely conflated, of course. For a functionalist, such as Radcliffe-Brown, the problem of rationality does not come up in the standard form discussed in this entry. The functionalist focuses on explaining the existence and persistence of certain social practices in terms of the effects they produce, understood against a theory of necessary social functions (see Functionalism in social science §2). Questions of the rationality of belief as informing the practices is at best of secondary interest.

In contrast, symbolists, such as Beattie, and with some qualifications, Sperber, are primarily concerned with understanding beliefs. They typically see human actions as having an expressive dimension. Beliefs that taken literally as translated seem to be indicative propositions, and problematically rational as such, symbolists interpret as having essentially symbolic meaning. They argue that this dimension of meaning can only be fully recovered by understanding the symbolic or expressive content of the ritual or practice in which the belief is embedded. Once the symbolic meanings of the belief and practice are recovered, there are no further issues of rational evaluation to be raised.

Many see a basic problem with the functionalist and symbolist approaches. In neither view is it clear how to connect the agents’ reasons to their actions. Rational agents act for reasons, expressed in terms of their beliefs and desires as they understand them. They do not typically act to satisfy the function assigned to a practice by the functionalist. Nor, for the most part, do they understand their beliefs as primarily expressive or symbolic utterances. However, reasons as understood by the agents themselves do not enter into the functionalist’s or symbolist’s explanation of the rationality of the action. Thus, agents do not appear as rational actors on the first level noted above, where actions are brought about for and in light of reasons. Practices may be understood as rational, given these approaches, but we lose our grip on the agents as rational actors.

8 The fideist position

The third position, the fideist, is most associated with Winch and influenced by Wittgenstein's remarks on Frazer's *The Golden Bough* (Wittgenstein 1979). Wittgenstein criticized Frazer in rather harsh terms for interpreting early magical and religious accounts as if they were putting forth theories to explain the world, and then judging them to be inferior, mistaken accounts at best. It is nonsense, Wittgenstein argued, to treat, as he thought Frazer did, magical accounts as a kind of false physics. Rather, we should attempt to appreciate their ritualistic and spiritual meanings as part of a culture. According to the fideist, the intellectualist imposes Western categories on other cultures too uncritically and reaches judgments of irrationality too easily. What is crucial for the fideist is attempting to understand, to as great an extent as possible, beliefs and practices as they are understood from within the other culture, or to use the Wittgensteinian term, the other form of life. Unlike the symbolist, the fideist does not want to impose a level of symbolic meaning on beliefs that is not accessible to the speakers themselves. We are to assume that agents act for reasons that they understand, but we have to be very careful about how we establish the meanings of propositions stating the agents' beliefs and desires.

Furthermore, the fideist is reluctant to make judgments of rationality or irrationality. Just as we have to understand meaning from the point of view of the agents, so we have to understand their concepts and norms of rationality. Those are the only norms that can properly be used to evaluate their beliefs and practices. Even such basic logical concepts as consistency and contradiction cannot be assumed to be held in common with us and we should not impose our concepts on others who may have very different ones. Thus, the fideist position seems to endorse a form of cultural relativism.

The fideist, then, would argue that we must stop at level two judgments of rationality, that is, judgments of the rationality of actions relative to the norms of the culture in which they occur. For the fideist, level three judgments are either incoherent, wrong, or pointless. They are incoherent if it is thought that there can be culture-independent judgments. For the fideist, all judgments are relative to a culture or form of life; we simply have to give up the idea of 'the view from nowhere', to use Nagel's phrase. Third level judgments are wrong if, thinking we are being neutral, we merely impose our norms on others. Norms and concepts cannot, according to the fideist, be exported beyond the boundaries of the form of life in which they function and have meaning. And such judgments are pointless if all we are doing is using the norms of the agents' own culture. In that case, there is no distinction between level two and level three judgments, for the norms of rationality of a culture are of course going to be judged rational from within that culture.

In so far as fideists endorse some form of relativism, they will have to contend with the various criticisms aimed at relativism in general. For instance, it is not clear that the fideists' relativism is consistent with a Davidsonian approach to interpretation. Fideists have served the important function of warning the intellectualist, and in a different way, the symbolist against uncritical use of our categories to understand others. If other cultures do have very different cultural norms and practices, we have to attempt to understand them in their own terms. It may be, for instance, that a very different culture has nothing quite analogous to Western science, or for that matter, to the practice of Western religion. What may seem initially like a rather irrational form of science might be better understood in very different terms. In cases where practices seem all but incommensurable, judgments of comparative rationality may be out of place.

Still, despite the objections of some fideists, judgments of rationality may have their place even here. What is needed is a way of comparing across cultures practices that initially seem to resist being placed in the same categories. Some have suggested that a properly developed theory of human interests might afford such common ground. Furthermore, to the degree that one is convinced by Davidson's theory of interpretation, one cannot allow for different basic norms of rationality. It would follow, then, that there are norms of rationality with which one can judge the beliefs and practices of others (and of ourselves), once the beliefs and practices are properly understood.

Rationality of belief

Humans, claimed Aristotle, are rational animals. However, recent psychological studies purport to show that people systematically deviate from canons of logic, probability theory, decision theory and statistics. Interpretations of these studies differ about the nature of the errors: on some views, there are no real errors at all; on others, subjects are distracted from applying the proper formal rules by, for example, the influence of conversational expectations. A common suggestion is that the reasoning subjects display is nearly optimal, once we take account of our severe cognitive limits in realistic circumstances or in our evolutionary history.

These diverse views reveal two opposed tendencies in constructing a theory of rationality. One favours the formal rules which, if violated in real life, could have serious consequences. The other holds that people's actual practice provides the only standard. A popular model, incorporating both tendencies, holds that those principles or norms are justified that yield the best balance between our reasoning intuitions and the demands of theory or system.

1 Empirical studies of reasoning

Reasoning is central to the acquisition and improvement of our beliefs. If a belief is recognized as sustained through defective reasoning, it is not rational to maintain the belief. Consequently, a good deal of interest attends recent psychological studies (for example, Wason and Johnson-Laird 1972; Kahneman *et al.* 1982) that purport to show serious and systematic deviation from canons of logic, probability theory, decision theory and statistics. Although these canons do not function as theories of what *should* be believed (Harman 1986), they do provide serious *constraints* on reasoning and inference. Because these recent studies seem to show people violating these constraints, they are troubling and important.

Four of the best known of these studies are: the 'selection task', which investigates deductive reasoning with conditionals; the 'conjunction problem', the 'base rate' problem, and the 'preference reversal' problem, all of which involve features of probabilistic reasoning. (The reader is advised to try each one, before reading the results.)

The selection task. Four cards are placed in front of each subject.

$E \qquad K \qquad 4 \qquad 7$

The subjects know that on one side of each card is a letter and on the other a number. The following rule is presented: if a card has a vowel on one side, then it has an even number on the other. The task is to pick out just those cards that need to be turned over in order to determine whether the rule is true or false. Almost all subjects turn over the E card, and many the 4. More crucially, few turn over the 7 card (Wason and Johson-Laird 1972).

Conjunction. Subjects are offered the following personality sketch:

Linda is 31 years old, single, outspoken and very bright. She majored in philosophy. As a student, she was deeply concerned with issues of discrimination and social justice, and also participated in anti-nuclear demonstrations.

They are then asked to rate the probability of the following statements:

(1) Linda is a psychiatric social worker.
(2) Linda is a bank clerk.
(3) Linda is an insurance salesperson.
(4) Linda is a bank clerk and is active in the feminist movement.

The main finding in the conjunction study is that 'Linda is a bank clerk and a feminist' is judged more probable than that 'Linda is a bank clerk' (Tversky and Kahneman 1983).

Base rates. Subjects are told that a cab has been involved in a hit-and-run accident at night. They are given the following data:

(1) 85% of the cabs in the city are green and 15% are blue.
(2) A witness identified the cab as blue.
(3) The court tested the reliability of the witness under the same circumstances that existed on the night of the

accident and concluded that the witness correctly identified each one of the two colours 80% of the time and failed 20% of the time.

What is the probability that the cab involved in the accident was blue rather than green? Subjects largely assign the probability 0.8; that is, their judgment is based wholly on the reliability of the witness. But if the base rates (0.85 and 0.15) are used as prior probabilities, then the answer is 0.41 (Kahneman *et al.* 1982: 156-7).

Preference reversal. Subjects are offered two gambles (at different times):

(a) Choose between
gamble 1. £500,000 with probability 1; and
gamble 2. £2,500,000 with probability 0.1, £500,000 with probability 0.89.
(b) Choose between
gamble 3. £500,000 with probability 0.11; and
gamble 4. £2,500,000 with probability 0.1.

The study is cited as of 'preference reversal' because it is generally found that subjects prefer gamble 1 to gamble 2 in situation (a), while they prefer gamble 4 to gamble 3 in situation (b). Yet, one should prefer gamble 1 to 2 if and only if one prefers gamble 3 to 4, since they are equivalent. (See essays by Allais, Ellsberg, Kahneman and Tversky, and Savage in Moser (ed.) (1990).)

In each case the violation is of a simple and familiar formal principle. In the selection task, a statement of the form 'If *p*, then *q*' is incompatible with one of the form '*p* and not-*q*' (for example, a vowel on one side, and an odd number on the other). In the conjunction task, the probability that someone satisfies a *conjunction* of properties (being both a feminist and a bank clerk) cannot be greater than the probability of their satisfying one of the conjuncts *separately* (being a bank clerk alone).

The correct way to calculate the probability in the base-rate case is by using Bayes' theorem, which says that the posterior (or, conditional) probability of a hypothesis *h* (the cab was blue) given evidence *e* (the witness saw a blue cab) is determined by how likely *e* and *h* are to be true simultaneously and by the probability of *e* being true at all. But subjects ignore the likely colour of the cab and judge only on the basis of the reliability of the witness, disregarding the probability of the cab's actually being blue. In the 'preference reversal' case, one is assigning a utility to an outcome in one gamble that is inconsistent with the utility assigned to it in the other (see Rational choice theory; Rationality, practical).

2 Interpretation

Some hold that we should not treat these results as deserving a uniform account. In particular, dispute has focused on whether in the base-rate studies, subjects' answers are, in fact, incorrect. For example, in an article that generated much controversy, Cohen (1981) argued that the Bayesian analysis using the base rates as prior probabilities would be correct, if the question concerned repeated or long-run samplings. But subjects reasonably interpret their task as the determination of the colour in this particular accident. From the information given, only the reliability of the witness is relevant to that determination. The base rates would also be relevant if they were not mere frequencies, but reflected causal factors involved in an accident, for example, if the 85-15 difference was a difference in respective accident rates. In fact, when the base rates have a natural causal explanation, it was found that subjects *do* incorporate them into their answers (Kahneman *et al.* 1982: essays 8, 10).

Among further interpretational questions, four deserve mention.

(1) The task may generate conversational implicatures that lead subjects away from the target formal representation (see Grice 1989; Sperber *et al.* 1995; Implicature). For example, the statement 'Linda is a bank clerk' in the context would appear conversationally to implicate that Linda is a bank clerk *and not a feminist*. Experimenters try to control for conversational inferences. For example, instead of offering 'Linda is a bank clerk' they might offer the alternative of 'Linda is a bank clerk, who may or may not be a feminist'. Even so, it remains questionable whether habitual conversational expectations are so easily set aside (Adler 1991).

(2) Some variant presentations yield different patterns of response. In the base-rate or conjunction studies,

presentation in a *frequency* format (citing *number* of cases, rather than *ratios* or *probabilities*) leads to many more subjects responding according to a straightforward probabilistic analysis (Girgerenzer 1991).

(3) In the case of preference reversal, alternative understandings may be legitimate so that, for example, the achievement of certainty is itself valued, rather than being treated as just another degree of belief (Schick 1991).

(4) Most dramatically, at least in the selection task, when the problem is posed for a natural setting, there is enormous improvement. In one set-up there is an array of envelopes (face down and sealed; face down and unsealed; face up with a 50 lire stamp on it; face up with a 40 lire stamp on it) and the rule 'If a letter is sealed, then it has a 50 lire stamp on it'. Once subjects are presented with a realistic model, they readily recognize that the envelope with the 40 lire stamp on it (the analogue of the '7' card) must be turned over. What is crucial is the realism of the conditional, not its familiarity (Wason and Johnson-Laird 1972). In particular, striking improvement occurs when the conditional captures a connection or rule of practices involving permissions or obligations. Recent work treats such rules as modularized, products of social exchange important in our hunter-gatherer evolutionary history (Cosmides and Tooby 1996).

These interpretational questions suggest that subjects orient the problems to common expectations or habits, rather than representing their task as clearly calling on formal principles. What is it about the task or set-up that directs subjects away from representing the problem so that the familiar formal rules are seen as applicable?

The guiding thought in most answers is that these results actually reveal near optimal reasoning, given the demands on us for cognitive economy in the environments in which our reasoning capacities evolved. If subjects formed the logically equivalent contrapositive of the above rule, they would turn over the '7' card: since 'If that bird is a raven then it is black' is equivalent to 'If that bird is non-black then it is a non-raven'. But normally the contrapositive of an ordinary conditional as it involves the complement class of a natural class is not itself a natural class: black ravens form a natural class, but non-black, non-ravens do not. We do not ordinarily test whether ravens are black by examining non-black things (for example, pennies) to see whether they are non-ravens (see Confirmation theory; Hempel, C.G. §2).

Nor do we ordinarily reason with the kind of *static* information characteristic of these studies. Although other studies do reveal a tendency towards belief perseverance or conservatism (Kahneman *et al.* 1982: essays 9, 15, 25), in general dynamic or continuous reasoning is much less investigated. Where feedback from the environment is expected, the cost of initial errors may be compensated for, so long as we remain open to subsequent modification or correction (Hogarth 1986).

In reflecting on what these studies reveal about the rationality of our beliefs, there are two opposed tendencies. One says that to violate or bypass the formal rules is to commit errors, whose analogues in real life can be serious. The other says that the formal rules, and the experts in the corresponding formal systems, are not authoritative on how it is reasonable to understand the problems: we are. Suggestive of a 'naturalized epistemology', there is no authority about reason apart from the actual reasoning processes or intuitive judgments of human beings (see Naturalized epistemology).

A popular model, incorporating both tendencies, holds that those principles or norms are justified that yield the best balance between our reasoning intuitions and the demands of theory or system. The model has been especially attractive to those who hold that it is an a priori truth that canons for human reasoning must reveal its rationality, since they are derived from human judgment, at least when suitably idealized (Cohen 1981). However, the balance model supports this strong a priori rational view only if the judgments in these studies do count as telling intuitions and these intuitions are sufficiently systematic. But given the dependence on changes in content, this is disputable. Moreover, formalization allows the generation of powerful theories based on very weak axioms: the resulting gains in systematicity could quickly outweigh any appeals to the kinds of intuitions revealed by these psychological studies.

Rationality, practical

Whereas theoretical reason is that form of reason that is authoritative over belief, practical reason is that form of reason that applies, in some way, to action: by either directing it, motivating it, planning it, evaluating it or predicting it. Accounts of practical reason include theories of how we should determine means to the ends we have; how we should define the ends themselves; how we should act given that we have a multiplicity of ends; how requirements of consistency should govern our actions; and how moral considerations should be incorporated in our deliberations about how to act.

Economics has provided, in recent times, what many regard as the most compelling portrait of practical reason, called 'expected utility *theory' (hereafter 'EU theory'). On this theory, rational action is that action which yields the highest expected utility, which is calculated by measuring the utility - or the 'goodness' or 'badness' - of the possible outcomes of the action, multiplying the utility of each outcome by the probability that it will occur, and, finally, adding together the results for all the possible outcomes of each action. The action that has the highest expected utility is the rational action. Other technical representations of practical reason have been explored in the branch of social science called 'game theory', which studies 'strategic' situations in which the action that is rational for any agent depends in part on what other agents do.*

A theory of practical reason can have one or more of several different goals. If it sets out how human beings actually *reason, it functions as a* descriptive *theory of reasoning. If it sets out a conception of how our reasoning* ought *to proceed, it functions as a* normative *theory of reasoning. Theories of reason can also be about actions themselves: if a theory presents a conception of the way our actions should be intelligible or consistent or useful (regardless of the quality of the deliberation that preceded it), it functions as a (normative) theory of behavioural rationale. If it merely presents an account of consistent action that allows us to predict the behaviour of an agent whose previous actions fit this account of consistency, it functions as a descriptive theory.*

One might say that whereas theoretical reason is supposed to pursue truth, practical reason is supposed to pursue some sort of good or value in human action. Theories that take rational action to be that which achieves, furthers or maximizes (what is regarded as) good, are consequentialist *or* teleological *theories. Theories that believe rational action must sometimes be understood as action that has an intrinsic value or 'rightness' regardless of how much good it will accomplish or manifest, are non-consequentialist or non-teleological conceptions of reason. If the theory defines reason as that which serves ends defined by something other than itself, it is an* instrumental *conception. If it allows reason to have a non-instrumental role, itself capable of establishing at least some of our ends of action, it is setting out a non-instrumental conception. Theories of practical reason that recognize the existence of a special moral reasoning procedure tend to represent that procedure as non-instrumental.*

Philosophers have disagreed about whether practical reason gives us a way of reasoning prior to choice that can actually motivate us to behave in the way that it directs. Many believe it lacks motivational power, so that it can only give us authoritative directives that must be motivated by something else (for example, by our desires). Finally, the study of practical reason also considers the variety of ways in which one can fall short of being rational; and issues about the nature and possibility of irrational 'weakness of will' have been central to this discussion.

1 Representations of practical reasoning

Historical suggestions. There have been many theories of the nature of practical reason over the years, going back to the Ancient Greeks.

Aristotle, although never offering a detailed theory of practical reason, made certain remarks in various of his writings that assimilated practical reasoning to a kind of logical reasoning. One example of (what are called) Aristotelian practical syllogisms appearing in Aristotle's *Nicomachean Ethics* (1147a5) goes as follows:

Dry food suits any human.
Such-and-such food is dry.
I am human.
This is a bit of such-and-such food.

Therefore, this food suits me.

But why is this syllogism an example of practical reasoning? On the face of it, it is a logical deduction, which is a form of theoretical reasoning. Aristotle can only claim it to be a form of practical reasoning if this logical deduction eventuates in some kind of imperative with authority over action. But in the argument presented above, the conclusion is not in imperative form, and the argument makes no direct connection between the conclusion (that this food suits me) and any actions or intentions to act that I do or should have. Nor does Aristotle tell us how reasoning, operating practically, would produce a connection between the conclusion of this syllogism and my actions or intentions.

In more recent times, philosophers have argued that practical reason produces imperatives of the form ‘If you desire *x*, then since *y* is a means to *x*, do *y*’. Immanuel Kant (1785) refers to these as ‘hypothetical imperatives’ (see Kant, I. §9). So on this view, a hypothetical imperative that is authoritative over action eventuates from practical reasoning, understood as a process by which we work out effective means to the given ends of an agent. To use Aristotle’s example, if I were hungry, I would engage in practical reasoning to determine a kind of food that suits me, where my reasoning would (if I had sufficient information about the world) eventuate in a hypothetical imperative of the form ‘If I am hungry, I should eat such-and-such dry food’.

But if this is how we understand practical deliberation, it seems little different from theoretical reasoning. On this view, deliberation is primarily a matter of working out causes and effects, and if that is all reason is doing, it appears to be functioning merely theoretically, using the principles of causal reasoning. Indeed, one interpretation of the theory of reason offered by David Hume (1739-40) is that reason only has a theoretical function, and thus is a purely informational faculty, working out relations of ideas and causal connections, with no authority or motivational efficacy with respect to action (see Hume, D.). So interpreted, Hume is saying that there is no such thing as a form of reason that chooses or judges action - but only a form of reason by which we form and judge belief that is (merely) informational with respect to action. However, even among those who accept the validity of both practical and theoretical reason, there has been ongoing dispute about whether these forms of reason are genuinely distinct; even assuming that they are not, there is disagreement: some - including Plato (in the *Republic*) - have held that practical reason derives from theoretical, others (for example, Goldman 1986) have said that the theoretical derives from the practical, and still others (for example, Kant 1785) have claimed that practical reason and theoretical reason are two forms of the same thing.

Expected utility theory: the basic idea. Defenders of the reality of practical reason have attempted to define practical reasoning so as to show how it differs from theoretical reasoning. The most popular of these theories in modern times is highly mathematical, in ways that highlight how complicated and intricate idealized decision making with respect to action might be. Called ‘expected utility theory’, it was developed by John von Neumann, Oskar Morgenstern and Leonard Savage.

To get a rough idea of what the theory says, imagine yourself in a situation where you do not know for certain what the results of your various alternative courses of action might be. Suppose, for example, that you have the option to buy a lottery ticket: if it is the winning ticket, you will receive a million dollars; if it is not, you will receive nothing and you will lose the money (let us say $10) that it cost you to purchase the ticket. If you do not buy the ticket at all, you will not win, but neither will you lose. So you have a choice between a risky action (buying the ticket) and an action the results of which you know for sure, which avoids both losses and gains. What do you do? The idea behind expected utility theory is that for each possible action available to you, you develop some measure of the ‘goodness’ or ‘badness’ of that action by, first, evaluating the goodness or badness of each possible alternative outcome, second, multiplying this value by the probability of that outcome’s occurring and, finally, adding together the products for all the possible outcomes of each action.

So, in our lottery example, you proceed, first, by developing a measure of the goodness of winning the lottery prize and the badness of losing the prize and being $10 out of pocket. As we shall discuss in §3 below, there is more than one way that people who have endorsed expected utility theory have thought such a measure should be constructed; the result is standardly referred to as the ‘utility’ of the outcome. In general, positive, pleasurable or beneficial outcomes of an action are represented using a positive number, whereas negative, costly or painful results are represented with a negative number.

Second, you should multiply each of these numbers by the probability of winning the lottery or losing the lottery. The probability of a sure thing is taken to be 1; in our lottery case, this means that the probability of gaining nothing if you do not buy a ticket is 1. Note also, however, that if you do buy a ticket, it is a sure thing that you will either win the lottery or not win the lottery, meaning that the sum of the probabilities of these mutually exclusive outcomes should equal 1. Hence if *p* is the probability of winning the lottery, we can express the probability of not winning the lottery as $1 - p$ (see Probability theory and epistemology).

Third, you should add together the products of the utility and probability numbers to get the 'expected utility of the action of buying the lottery ticket'. So, if the probability of winning the lottery is *p*, and the probability of not winning the lottery is $1 - p$, and if (as economists often do) we identify utility with money, so that the utility of winning the lottery is 1,000,000 and the utility of not winning the lottery is -10, the expected utility (EU) of buying the lottery ticket is

$$(1,000,000)p + (-10)(1 - p).$$

After determining the EU of buying the ticket, you then compare it to the expected utility of not buying the ticket. Since you will not win or lose anything if you do not buy the ticket, the utility of the result of this action is 0. That number is multiplied by the probability 1 (since it is a sure thing that you will neither win nor lose if you buy the ticket), making the expected utility of not buying the ticket equal to 0. So if the expected utility of buying the ticket is greater than 0, you should buy the ticket, despite the risk of losing, and if the expected utility of buying the ticket is less than 0, you should not buy the ticket despite the chance of making great gains. In a way, one can think of expected utility theory as telling you how to determine, in each of life's risky situations, when and if a certain course of action is a 'good bet' or a 'bad bet' given the possibilities.

2 Categories of theories of practical reason

Descriptive v. normative theories of reasoning and rationale. In evaluating whether expected utility theory is a successful theory of practical reason, we should consider, first, what a theory of practical reason should be expected to do.

There have been a number of distinctive tasks that philosophers have thought their theories of practical reason must perform. For example, it is commonly thought that there is a kind of deliberation or reasoning process that does or should occur in the minds of agents prior to action, which authorizes that action and may also motivate it. Theories that describe how we *actually* deliberate prior to action are *descriptive* theories of reasoning. Theories that prescribe how we *ought* to deliberate prior to action (where this may diverge substantially from our actual reasoning process) are *normative* (or *prescriptive*) theories of reasoning.

Theories of behavioural *rationale* are a kind of normative theory that specifies one or more standards by which the behaviour of an agent is evaluated. It is a common (and understandable) presumption of many that the principle(s) used to judge behaviour should be the same as the principle(s) on which human reasoning is based prior to choice, and normative versions of theories of reasoning often function as theories of behavioural rationale. None the less, it may be that the correct conception of behavioural rationale is one that, given human constraints and limitations, is too difficult for us to use as a reasoning process, in which case, the theory used to judge the rationality of behaviour would diverge from the (less complicated) reasoning procedure human beings would be able to use prior to action.

A *predictive* theory of reason predicts the behaviour of an agent who satisfies certain consistency requirements. Such a theory may be (and often has been) linked to a theory of rationale when these consistency requirements are taken to manifest a certain normatively desirable consistency in choice. Some might speculate that if a predictive theory made successful predictions of an agent's choices, then that success would provide evidence that the agent (in some way) mentally followed the procedure described by that theory to make those choices, so that it was (in some way) a description of the reasoning processes upon which the agent operated. But the success of these predictions does not require that one draw this descriptive conclusion, and might be explained in other ways.

Two further distinctions in practical reason. There are important further issues concerning how a theory of practical reason should bear upon action. For example, should rational actions be understood as those actions that promote (what are regarded as) good objects or good states of affairs? Or as those actions that are, in some way,

intrinsically valuable or right, regardless of the good they generate? Those theorists who believe that rational actions must be defined as those actions that maximize, achieve or promote the good have a *consequentialist* or *teleological* conception of reason. In contrast, *non-consequentialist* theorists believe that a rational action has certain characteristics that make it rational other than its tendency to promote the good. They try to define rational action, at least in part, by reference to principles of what might be called inherent rightness.

Different from this distinction is that between *instrumental* and *non-instrumental* conceptions of reason itself. An instrumental conception takes reason to serve ultimate goals that are set by something *other than reason itself*. (Hume is often considered to be the source of this idea.) An instrumental theory can allow the possibility that reasoning can set goals by functioning instrumentally. That is, we can distinguish between *motivated* ends, that is, ends that are means to the attainment of other ends, and unmotivated ends, that is, ends that are not means to the attainment of other ends. Many instrumental theories accept that reason can at least fix our motivated ends; others deny even this possibility. All of them, however, agree that our unmotivated ends are fixed by non-rational forces within us, for example, our basic or innate passions or desires (see Desire).

Nor need an instrumental theory be committed to the claim that the only form of reasoning is means/end reasoning; there are other tasks that reason can perform consistent with a denial of a non-instrumental role for reason. For example, practical reasoning can include not only deliberation about instrumentally effective means to ends, but also deliberation concerning the most convenient, economical, or pleasant way of satisfying some element in an agent’s motivational set, as well as deliberations with respect to time-ordering, or weighting of conflicting desires. It is only the non-instrumental fixing of ends that the instrumental theory leaves beyond the province of rational criticism.

Non-instrumental theories of reasoning or rationale, while admitting reason has an instrumental component, also ascribe to reason a role in defining unmotivated ends of action. Such views may hold, for example, that certain things are worth having for their own sake (for example, appetitive pleasure, comfort, aesthetic appreciation, certain sorts of accomplishment) and that practical reason is capable of recognizing their appropriateness as (unmotivated) ends of human action or activity.

3 The interpretation of EU

With these distinctions between kinds of reasons in mind, we can ask whether EU theory is a successful portrayal of practical reason. It all depends upon how one interprets the theory and, surprisingly, it has been interpreted in many different ways.

EU theory can be either an instrumental or a non-instrumental theory of reason, depending upon how one understands the source of the measure of the ‘utility’ or goodness of the outcomes used to evaluate the expected utility of the actions being assessed. Suppose, for now, that we adopt the account of Jeremy Bentham (1823) that regards this measure as a way of assessing the amount of pleasure or pain that one will receive from the results of an action. In this case, the goodness or badness of any outcome is defined by the way the agent experiences that outcome, where this experience has nothing to do with the agent’s reasoning process. Pleasure and the absence of pain can therefore be understood as the agent’s good (a good that, with each action, the agent attempts to achieve or maximize), where the content of this good is not in any way determined by reason operating non-instrumentally. Expected utility theory, on this view, is merely an account of the reasoning process we use in attempting to maximize this good, and thus should be understood as an instrumental theory.

However, von Neumann and Morgenstern (1944) developed a notion of ‘utility’ that is deliberately not meant to refer to an experiential state or to be an interpersonal measure of such an experiential state. The notion of preference can be (and has been) understood either as a mental state (for example, a kind of disposition to choose), or as something not merely revealed by, but actually consisting in, a person’s publicly observable behaviour (commonly referred to by economists as the idea of ‘revealed preference’). In their development of EU theory, an agent’s utility function attempts (merely) to represent an agent’s preferences understood in either of these ways, but the theory does not offer any explanation of why the agent has these preferences. Hence the theory leaves open the possibility that what an agent prefers may be the result of reason operating non-instrumentally. Only a psychological theory of preference formation could tell us whether reason does or does not play a role in determining an agent’s preferences (interpreted in either of the ways just mentioned). This means that von

Neumann and Morgenstern's EU theory can receive either an instrumental or a non-instrumental interpretation, depending upon the kind of psychological theory of preference formation appended to it.

Interestingly, however, von Neumann and Morgenstern appended no such psychological theory to their theory. Both were influenced by the philosophical position called logical positivism, which advocates that theories, to be scientific, must concern only that which is publicly verifiable - something that behaviour and choices seem to be, unlike deliberation or inner experiences (see Behaviourism, analytic; Logical positivism). However, a behaviouristic interpretation of the theory (which would embrace the idea of revealed preference) precludes us from developing it in a way that determines whether it is instrumental or non-instrumental.

Von Neumann and Morgenstern's non-psychological understanding of their theory is connected to their interest in developing a theory that could function *predictively*, regardless of any use it might have as a theory of reasoning or behavioural rationale. On their view, we interview or observe a person in order to get them to (arbitrarily) assign utility numbers to certain outcomes which they know they will get. Call these 'riskless prizes'. Once we know a person's assignments and once we know that their preferences satisfy certain seemingly weak axioms (defined more fully below), we can predict their preferences in situations where risk is involved. That is, we do not have to ask them what their preferences are in these risky situations - this can be determined for them from our computation. Moreover, our computations do not require that they actually reason using the expected utility formula - indeed, they may be agents that do not engage in reasoning at all. As long as we know that their preferences conform to certain axioms, we know they will make their choices as if they were such a reasoner, and that is good enough for us to predict their choices, regardless of whether or not they actually use the EU reasoning process.

4 The axioms of EU

There have been two important types of axiomatization of expected utility theory: the one that was originally developed by von Neumann and Morgenstern (1944), which relies on objective probabilities, and a second kind developed by Savage (1954), using Frank Ramsey's idea (1931) that we can define probabilities subjectively from information about the agent's preferences (see Ramsey, F.P. §2). We will consider here only the following rough, non-technical statement of von Neumann and Morgenstern's axioms relying on the idea of objective probabilities.

(1) The *completeness* (or ordering) axiom specifies that all the objects over which we have preferences can be compared or ordered. To be precise: for any prizes *a* and *b*, $a > b$ or $b > a$ or they are indifferent.
(2) The *transitivity* axiom tells us that if you prefer, say, apples to oranges, and oranges to bananas, you will also prefer apples to bananas. To be precise: for any prizes *a*, *b* and *c*, if $a > b$ and $b > c$, then $a > c$.
(3) Suppose you can participate in a compound lottery (that is, a lottery that has another lottery as at least one of its prizes), where there is some chance that you will ultimately win a million dollars rather than nothing. Suppose you figure out the chance you will get the million. Call this probability *p*. The *reduction of compound lotteries* axiom says that you will be indifferent between this compound lottery and a simple lottery in which the chance that you will win the million rather than nothing is also *p*. This axiom is mathematically necessary in order for von Neumann and Morgenstern to prove their conclusion.
(4) Suppose there are three prizes *a*, *b* and *c*. The *continuity* axiom says that if *a* is preferred to *b*, and *b* is preferred to *c*, then there will be probabilities such that a person will be indifferent between *b* and a lottery with *a* and *c* as prizes. This indifference depends upon the probability of getting *a* being great enough to outweigh the risk of only getting *c*, but not so great that the person would prefer the lottery over *b*, nor so small that the person would prefer *b* over the lottery.
(5) The *independence* (or substitutability) axiom says, very roughly, that if a person is indifferent between two prizes, *a* and *b*, considered alone, they are also indifferent between two lotteries that are exactly the same, with the exception that in one of them prize *b* is substituted for prize *a*. (This axiom is roughly equivalent to what Savage calls the 'sure thing' principle in his axiomatization of EU theory. The only difference is that Savage's principle does not assume objective probabilities, allowing for the determination of a decision-maker's subjective probabilities from his utilities.)
(6) The *monotonicity* axiom says that, between any two lotteries involving only the most and least preferred alternatives, you should not prefer the lottery that renders the least preferred alternative more probable.

Many philosophers, economists and social scientists have wanted to revise von Neumann and Morgenstern's theory explicitly to make it into a theory of reasoning or a theory of behavioural rationale. These theorists have added psychological theories or normative interpretations of the axioms, so as to transform EU theory into what they regard as a plausible descriptive or normative theory. For example, Savage considers the theory a normative conception of both reasoning and rationale, whatever predictive value it might have. Other theorists (such as Kahneman and Tversky 1990) have explored the extent to which the theory might succeed as a descriptive account of human reasoning, generally reaching the conclusion that some of EU's axioms are not widely followed (especially the independence axiom, which assumes that what we do is not affected by whether, for example, we see a glass as half full or half empty), meaning that the theory, on their view, is best construed as a normative rather than a descriptive conception of reasoning (see Rationality of belief).

If this theory is construed either as a theory of reasoning or as a theory of rationale, is it an instrumental or a non-instrumental theory? As noted earlier, it can only be construed as instrumental if its supporters introduce a psychological theory that specifies that all ultimate or unmotivated ends of action are set by something other than reason. Yet the addition of such a theory may seem initially precluded by the structure of EU theory, which makes it easy to give it a non-instrumental interpretation. Consider that EU theory makes a subject's preferences the definers of the ends of their action. However, it would seem the theory does not permit just any preference to be end-defining, but rather, only those preferences that satisfy the axioms of expected utility theory explicated above. But this appears to mean that the axioms play a role in fixing the ends of action by acting as a normative 'sieve' through which our preferences must pass in order to be considered 'end-defining'. Therefore, if these principles are part of what we mean by practical reason, does this not mean that reason is playing a role in setting our ends of action? If so, EU theory, in so far as it is defined in terms of these axioms, cannot be considered an implementation of the instrumental theory of reasoning. A number of theorists who regard EU theory as a normative account of human reasoning characterize the theory in ways that strongly suggest this non-instrumental interpretation - this even includes some who elsewhere treat it as an instrumental theory of reasoning.

Some philosophers, loyal to the instrumental characterization of practical reason, have argued that EU theory's reliance on these axioms is not really enough to make it a non-instrumental theory. For example, R. Nozick (1993) argues that admitting that these axioms play a role in defining our ends is only introducing consistency standards into our preference set, which is just 'one tiny step beyond Hume'. Yet by taking this 'tiny step' we invite the possibility that there are normative standards other than those of consistency (for example, moral standards) to which our desires ought to be subject (for on what grounds can we argue for some non-instrumental standards and against others?).

How might we argue that the EU axioms can be defended within a pure instrumental theory? One obvious way to try to do so is to claim that EU axioms can be instrumentally justified. On this view, the EU axioms prescribe consistency, and agents must have consistent preferences if they are to achieve the maximal satisfaction of whatever preferences they have. But even if the principle 'To satisfy ends, one must be consistent' is true, the EU axioms are not the only representation of consistency, so it seems one could satisfy the principle by using other reasoning theories with rather different axioms. Furthermore, an instrumentalist argument must avoid circularity: to defend the axioms as instrumentally justified, the argument cannot appeal to the desirable consequences of following the axioms, if that very appeal presupposes that these consequences are desirable as the objects of preferences that satisfy the axioms to be defended. Alternatively, the axioms of EU, or some other set of axioms, might be non-instrumentally justified as intuitively compelling or as cohering well with other intuitive principles of reason.

5 Challenges to expected utility theory

Many theorists have maintained, on the basis of empirical evidence, that human beings consistently violate some of the EU axioms (see, for example, Kahneman and Tversky 1990; Allais 1979; Ellsberg 1951; Rationality of belief). That evidence appears to show that, at the very least, EU theory fails as a *descriptive* account of our practical reasoning. And the violations of some of the EU axioms seem so intuitively reasonable that many theorists believe they show EU theory fails as a *normative* account of our reasoning. While the examples are too complicated to discuss here, it is important to note that there is a pattern to many of the purported violations. Peter Hammond (1988) and others have argued that the axioms of EU theory articulate the idea that we choose actions

(solely) by assessing the consequences of those actions, but violations of these axioms occur when people's choice of action results from certain non-consequential preferences they have - for example, preferences for the situation, action or process from which the consequences will result. Economists have called these *state-dependent* preferences. Does the existence of these preferences show not only that EU theory is the wrong portrayal of practical reason but also, more fundamentally, that any successful descriptive or normative theory of practical reason will have to be non-consequentialist, relying on axioms of choice that recognize that sometimes we choose to act for reasons other than the desirability of the consequences of these actions?

Some advocates of the idea that we are consequentialist reasoners answer this last question negatively. They have proposed that purported counterexamples to EU theory can be accommodated once we reinterpret them to show that hidden in the examples are possible consequences to which people have positive or negative attitudes. If this strategy works, it would support the idea that, if we understand the consequences in any choice situation in an appropriately broad way, no human being whom we would consider rational will violate the (consequentialist) EU axioms in their choices. One worry that even the defenders of this strategy have voiced is that it might work too well - allowing us to redeem any violation of the axioms by finding some hidden consequence to which the purported violator is actually responding. Some theorists (particularly John Broome 1991) try to avoid the problem by arguing for principles that specify when a rational agent must be indifferent between two outcomes. Such principles prohibit us from postulating hidden consequentialist attitudes that, if recognized, would mean the agent was not violating the axiom after all.

Those theorists who believe that the purported counterexamples cannot be explained away have advocated rejecting one or more of EU theory's axioms, so as to develop a revised theory that attempts to be a better descriptive or normative theory of reasoning or behavioural rationale. For example, Mark Machina (1991) rejects the independence axiom, and Graham Loomes and Robert Sugden (1982) drop the transitivity axiom. These revised theories are not, however, radical departures from EU theory, and retain much of the structure of that theory.

6 Contemporary non-maximizing alternatives to expected utility theory

One central assumption of EU theory is that rational action is maximizing action: faced with a multiplicity of ends, we are supposed to try to maximize their satisfaction. But some critics of the theory insist that rational action with respect to a multiplicity of ends often permits, and sometimes even requires, that we refrain from maximizing.

For example, Herbert Simon (1982) has argued that we should understand reason in a non-maximizing way because human beings operate subject to limitations and constraints that make effective maximization impossible. These limitations and constraints come in two varieties: constraints on information-gathering relevant to action (for example, limited access, high costs of obtaining, and limited time), and constraints on computational ability (for example, limited memory, intellectual disabilities, high costs of difficult calculations, and slowness of calculation relative to time allowed). Because of these constraints, Simon argues that human beings do not (and should not) reason by straightforwardly maximizing. Instead he says they do (and should) use certain shorthand reasoning procedures that yield good results given these constraints and limitations. Simon calls reasoning using these shorthand procedures 'satisficing'.

However, Simon's satisficing can be understood as consistent with a maximizing conception of reasoning if it is defended as a form of reasoning used by agents interested in maximizing preference satisfaction while subject to the above constraints. On this view, agents maximize to the best of their ability if they use these shorthand satisficing procedures. This position therefore represents a maximizing form of reasoning as a 'meta-rational' procedure that assesses possible operational reasoning procedures for those agents who are subject to certain constraints that make maximization too costly or too difficult to operate upon directly.

A more radical anti-maximizing theory that cannot be reconciled with an overall maximizing theory of reason is proposed by Isaac Levi (1986), who argues that our decision making must sometimes contend with unresolved conflict. On Levi's view, there are times when different options available to us are good in quite different ways (reflecting different moral, aesthetic, prudential, cognitive or political values), such that we cannot conclude that one of them is, all things considered, better than the other(s). Levi argues that when such conflict between values cannot be resolved, a rational agent cannot act so as to maximize one unified conception of the good (since there is

no such thing in these circumstances), but must instead act in a way that, given their evaluation of the options, is at least admissible. Levi's non-maximizing theory is none the less still a teleological or consequentialist portrayal of practical reasoning, in so far as rational action is construed as that which serves a goal.

An even more radical anti-maximizing portrayal of practical reason has been proposed by Michael Slote (1989). Slote holds that self-regarding rationality often permits or requires maximization with respect to our own good, but he also insists that we are sometimes rationally permitted and even have positive reason, on balance, to abstain from performing actions that we know will maximize our own good. On his view, if we are moderate in our desires, we can, for example, reasonably turn down a second dessert or a luxurious house - not because we think we would not enjoy or be better off with them - but because we consider our situation to be good enough and fine just as it is. Since it says that there can sometimes be reason on balance to prefer an action whose results are *less* good for one, Slote's conception of rationality is, strictly speaking, neither consequentialist nor teleological.

Jon Elster (1979) thinks about the issue of maximization in another way. Elster distinguishes between (what he calls) a *global* maximizer conception of practical reason and a *local* maximizer conception of practical reason. Local maximizers do whatever they judge best at the time of choice, but this means they have a 'myopic eye fixed to the ground' and cannot take into account 'what happens behind the next hill'. In contrast, a global maximizer can choose the worse option now, in order to be in a position to realize a far better outcome than the presently better option would yield. Unlike theorists who think of us as reflecting in some piecemeal fashion about how to satisfy effectively a set of desires as they present themselves to us at any given time, Elster's discussion points out that human beings need, and use, a conception of means/end reasoning that stretches out over time, permitting the rationality of enduring short-term losses in order to realize long-term gains.

The importance of reasoning long-term is, in the view of many theorists, connected to the idea of prudence. It is commonly (but not universally) thought that the practically rational person can not only choose effective means to ends, but also resolve on a course of action that will advance their interests in the long run, not merely the short run. Much of the literature in this area is inspired by the work of Thomas Nagel (1970). Some of it (see, for example, Derek Parfit 1984) explores the extent to which our conception of our own identity as persons is connected to reasoning with respect to the future (see Morality and identity).

How the idea of global rationality should be developed is controversial; some, such as David Gauthier (1986) and Edward McClennen (1990), have proposed that fully rational agents should sometimes remain 'resolute' in their intention to perform an action in order to achieve some desirable end, even in situations where conventional maximizing forms of reasoning would endorse another tempting alternative. Such resolution is rational on their view, when it would make possible benefits that can only be realized if the agent maintains the intention to perform this action. Gregory Kavka's 'toxin puzzle' (1983) gives us a way to illustrate their view: imagine that there is a millionaire who will give you a million dollars if you form the intention to drink a toxin that will not kill you but will make you ill, where this millionaire will give you the money before you have to drink the toxin, as long as they are satisfied that you have formed the intention to do so. Resolute theorists argue that, to get the money, you should form the intention to drink the toxin, and then drink it. However, other theorists dispute the rationality of resoluteness, and argue that a rational agent in the toxin example would conclude that it would be irrational to drink the toxin, and thus irrational to form the intention to do so (even though this means losing a million dollars). This view presupposes a theory of rational intention that makes resoluteness irrational. Theorists on both sides of this issue believe that intentions and actions must be linked, on pain of irrationality. However, resolute theorists believe that as long as it is rational to intend to perform an action, then it is rational to perform it, whereas critics of the idea of resoluteness maintain that one can only rationally intend to perform an action when it is actually rational to perform it.

7 Contemporary non-maximizing alternatives to expected utility theory (cont.)

Elster and others have also argued that conceptions of reasoning must go beyond maximization in order to reckon with the phenomenon of 'endogenous preference formation'. This term refers to the process by which agents modify or revise what they prefer in response to constraints their environment places upon them. For example, in Aesop's fable, the fox, who cannot reach the grapes he desires, finally decides that they must be sour anyway, so that he does not want them. Thus the fox changes his preferences when he discovers that he cannot satisfy them as they are. Endogenous preference formation may not only be a fact, but a normatively desirable response to our

environment. (Consider the advice given by Crosby, Stills and Nash in a popular song: ‘If you can’t be with the one you love, love the one you’re with’.) Note that this phenomenon would seem to be neither explained nor endorsed by EU theory, since it involves a (non-instrumental) form of reasoning explicitly concerned with establishing our ends of action, in ways that have nothing to do with the axioms of consistency that define EU theory.

Theorists have also proposed non-maximizing conceptions of reasoning for situations of complete uncertainty, that is, situations in which we cannot assign probabilities to the possible outcomes. In such cases, we cannot reason as expected utility maximizers, since doing so precisely requires that we know, or be able to estimate, the probabilities of possible outcomes of alternative actions. Some theorists (such as John Harsanyi 1976) have proposed that we should use the ‘principle of insufficient reason’ to derive probabilities that enable us to use an expected utility calculation. This principle tells us to estimate as equi-probable the possible outcomes of alternative actions most relevant to our decision making, and then use these probabilities in an expected utility calculation. However, other theorists (such as John Rawls 1971) have proposed the rationality of a ‘maximin rule’ of choice in at least some situations of complete uncertainty. This rule tells us to choose that action whose worst possible outcome is better than, or at least as good as, the worst possible outcomes of all the other alternative actions. This is generally considered a very conservative principle of choice under uncertainty.

Many theorists (for example, Bratman 1987) believe progress in understanding human reasoning should be made not by concentrating on maximization, but by thinking about the way our deliberation standardly involves planning. Constructing a plan involves a complicated and interconnected series of intentions about how to act. Plans would seem to be necessary in order to achieve a wide variety of ends, and in order to ensure that the achievement of one end does not foreclose the possibility of securing ends that are as important as, or more important than, the one we are presently concerned to achieve. This suggests that part of what it means to say that a person is practically rational is that they are a good planner, so that understanding practical reasoning involves specifying what ‘good planning’ is. This requires specifying, for example, what a ‘feasible’ plan is, when sub-plans are necessary, how extensive a good plan should be, and so forth. Those who are interested in constructing artificially intelligent beings are trying to specify the nature of rational planning in a way sufficiently detailed to allow the construction of a rational planner. Such a project, involving both philosophers and researchers in artificial intelligence, attempts to produce a form of practical reasoning that we would expect any agent to perform such that we would regard their operation in the world as ‘successful’ from a rational point of view (see Pollock 1995; Artificial intelligence).

8 Game theory

Other technical representations of practical reason exist within a subject called ‘game theory’, also invented by John von Neumann and Oscar Morgenstern (see Decision and game theory). To understand game theory, consider another distinction made by Jon Elster (1979), between ‘parametric’ and ‘strategic’ forms of reasoning. Consider the parametric reasoner Harry, who treats the environment in which he will act as a ‘given’, estimating how his actions will affect it. In contrast, the strategic reasoner Harriet regards her environment as containing agents whose choice of behaviour will depend in part on what they believe she will do, even while her choice of behaviour depends in part on what she believes they will do. Game theory concerns strategic reasoning because it depicts situations in which the ultimate payoffs to each player from possible actions available to them depend upon what the other player(s) will do. These situations can involve pure conflict - in which each player will only gain if the other(s) lose(s); or pure cooperation, in which each player will only gain if the other(s) gains; or games of mixed conflict and cooperation. In general, what counts as a rational solution in game theory has been the subject of considerable controversy.

A particularly famous game is the ‘prisoner’s dilemma’ or ‘PD game’. The name for this game comes from an early example of it in which the two players are prisoners who have jointly participated in a crime, and who are separately encouraged by the police to confess, thereby informing on their partner. If neither confesses they can only be convicted of a crime that yields 1 year in jail; if both confess they will both get 5 years in jail; if one confesses and the other does not, the confessor gets no years in jail but the person who fails to confess will get 10. In a game of this sort, each player prefers most the situation where he confesses but his partner does not, he prefers second the situation where neither he nor his partner confesses, he prefers third the situation where he and his

partner both confess, and he prefers least the situation where he does not confess but his partner does. While this fanciful example may make the game seem arcane, social scientists have argued that the PD game is very common in a variety of social situations, especially in a free market. For example, consider two companies, who each have the choice between colluding on prices (the equivalent of not confessing in the original example) or competing rather than colluding (the equivalent of confessing). The payoffs to each company make this a prisoner's dilemma. The seeming ubiquity of this game has persuaded many social scientists of the importance of studying it (see Rational choice theory §§2-3).

Many theorists have proposed that rational players in a prisoner's dilemma should reason using the idea of a 'dominant strategy'. According to this form of reasoning, the only rational choice is the non-cooperative action because no matter what the other player does, each player is better off not cooperating (if the other player cooperates, he gets his favourite outcome if he fails to cooperate; if the other player fails to cooperate, he avoids his worst outcome if he fails to cooperate). In this sense, not cooperating 'dominates' over cooperating. However, whether this is the right strategy for dealing with the prisoner's dilemma has been debated, and some theorists have proposed other ways of solving it. These include using expected utility reasoning and impartial (moral) reasoning - both of which may sometimes recommend that the parties in a PD game choose the cooperative option.

The PD game has also been compared to a puzzle called 'Newcomb's paradox'. Imagine that you are given the choice between taking the contents of an opaque box, or taking the contents of that box plus the contents of another, transparent box which you can see contains $101,000. The opaque box contains either a million dollars or nothing. Which of these it contains depends upon whether a powerful being (for example, some kind of god) capable of predicting behaviour with virtually 100 per cent reliability has predicted how you will behave. If the predictor has previously determined that you will choose only the opaque box, it has put a million dollars in it. If the predictor has previously determined you will choose both boxes, it has put nothing in the opaque box. How should you rationally choose? Some theorists (for example, David Lewis 1985) maintain that the prisoner's dilemma is an instance of Newcomb's paradox. More generally, those who discuss the paradox recommend different strategies for its resolution, including dominance reasoning and expected utility reasoning, that not only generate opposing advice, but also reflect different conceptions of the structure and aim of practical reasoning.

Another game much discussed in recent years is related to the prisoner's dilemma, and the resolution proposed for it seems interestingly suggestive of a kind of moral thinking. Imagine a situation in which a prisoner's dilemma between two or more players repeatedly recurs over time, and where the last recurrence is unknown. This is called an *iterated* prisoner's dilemma. Whereas, in a single-play prisoner's dilemma, the dominant strategy is not to cooperate, in an iterated prisoner's dilemma, cooperation is rational as long as each player has reasonable assurance that the other player will also cooperate (and will not lose too much by acting on the expectation that the other cooperates and is wrong). Some theorists have argued on the basis of computer models that agents who follow this 'tit for tat' strategy (cooperating with cooperative partners, not cooperating with non-cooperative partners) do better, overall, than players who follow other, less cooperative strategies. This strategy strikes many as having moral overtones (cooperation is rewarded, non-cooperation is punished), and some have speculated that moral responses and emotions, and moral ways of thinking, may well be explained by the way in which certain cooperative or non-cooperative forms of behaviour can be beneficial or harmful to human beings in common game-theoretic situations. Such reflections on the nature of strategic reasoning encourage the hope that future theorizing in game theory may serve to link rational and moral forms of reasoning. This link is also suggested by the work of theorists (such as J.F. Nash 1951; Gauthier 1986) who have explored the extent to which the rational resolution of some of these games might be understood to mimic the results of an ideal bargaining process.

9 Practical reasoning and standards

Most of the preceding theories of reason, including both the maximizing and the non-maximizing conceptions, assume that reason involves weighing the values of various considerations (for example, outcomes, actions) pertinent to our making a choice. This idea is naturally suggested by a teleological or consequentialist conception of reason. However, there are theories that represent rational action as involving the idea of satisfying principles or standards. On this view, a rational agent is one who, at least on some occasions, chooses how to act by applying the appropriate principle to their situation. Such principle-based reasoning can be assimilated to a consequentialist conception of practical reason if the justification for applying these principles is that doing so will help an agent to

achieve or maximize the good. Non-consequentialist theorists who reject this assimilation believe that at least some of these principles of right action cannot be justified by reference to any goal or conception of the good. On this view, in addition to whatever concerns an agent might have about how much good or bad an action might produce, they must none the less deliberate or act so as to satisfy these principles in order to be considered rational.

Some non-consequentialists believe that, to be rational, an action or policy must satisfy certain moral or political principles that prescribe ‘right conduct’ (some of which we will discuss in §10 below). Moreover, although some feminists (such as Lloyd 1984) have questioned whether the whole concept of practical reason reflects the assumptions and biases of our patriarchal society, Ruddick has argued that, in order to bring up their children, mothers must engage in reasoning that determines how to act so as to satisfy different and often conflicting principles (see, for example, Ruddick 1989). Apart from presenting a principle-based view of reasoning, her argument suggests there may be distinctive forms of reasoning appropriate for different practical activities (see Feminism; Feminist ethics).

Finally, Onora O’Neill (1989) has suggested that even though the object of instrumental reasoning is a goal, *how* that reasoning ought to proceed is defined by a variety of ‘principles of rational intending’, none of which is captured by EU’s axioms. Her account clearly implies the possibility of a non-consequentialist theory of instrumental reason.

10 Moral reasoning and weakness of will

A variety of moral theorists insist that practical reason has a moral aspect. Some theorists believe moral reasoning can be accommodated within the confines of expected utility theory since, on their view, moral reasoning is simply EU reasoning with other-regarding preferences. However, others insist that moral reasoning is not merely about how we satisfy our actual other-regarding preferences, but also (and more importantly) about defining how our preference set *ought* to take others’ interests into account.

For example, Kant (1785) believed that reason structurally involves a moral reasoning procedure that indirectly defines our ends of action. Kant calls this reasoning procedure the ‘moral law’ and one of his formulations of it is: ‘Act only on that maxim through which you can at the same time will that it will be a universal law’. When I follow this procedure, I universalize my maxim of action, converting it from the form ‘I will do *x* in circumstances *c* in order to achieve *y*’ to the form ‘Everyone does *x* in circumstances *c* in order to achieve *y*’. Then I evaluate that universalized maxim by determining, first, whether I will be able to achieve *y* by doing *x* in circumstances *c* in a world where everyone does *x* in *c* to get *y*; and second, whether I can ‘will’ the world in which everyone does *x* in *c* to get *y*. If a maxim meets this test, then I am permitted to act on it - otherwise, I have an obligation not to do so. This test procedure generates what Kant calls ‘categorical imperatives’, that is, imperatives that (in contrast to hypothetical imperatives) direct us to engage in certain forms of action, or direct us to refrain from certain forms of action, regardless of the desires or interests we happen to have (see Kantian ethics).

Kant’s account of moral reasoning is non-instrumental. The moral law acts as a kind of moral ‘filtering device’ through which maxims generated by our desires must pass, and his account is also non-consequentialist, because it presents reason not as that which weighs competing goods, but as that which answers to a certain principle of right conduct.

Another representation of moral reasoning is put forward by contractarian theorists. Contractarian reasoning procedures ask us to deliberate about a course of action, plan or policy by determining whether those affected by it (understood so that they are suitably impartial and equal in power) could agree to it or, alternatively, whether it would be something none of them could reasonably reject. This type of reasoning procedure is explicitly presented by John Rawls (1971) as a non-teleological or non-consequentialist form of reasoning, and the way in which it could be used to define ends of action also makes it a non-instrumental conception of reason. Other philosophers, such as David Gauthier (1986) and Thomas Scanlon (1982), have also insisted that contractarian forms of reasoning can define and illuminate the content, and perhaps even the motivational source, of moral behaviour (see Contractarianism).

Many contemporary moral philosophers called ‘utilitarians’, following Bentham, have endorsed various forms of a moral reasoning procedure labelled utilitarian, in which actions and policies are evaluated by determining whether

they maximize the welfare (understood by different theorists in different ways, for example, as happiness or preference-satisfaction) of members of a community (see Utilitarianism). Some utilitarians (for example, Harsanyi 1976) have linked a form of a utilitarian reasoning procedure (for example, the kind called ‘average utilitarianism’) to expected utility theory. Utilitarian forms of reasoning are classic examples of consequentialist theories of reasoning, in so far as actions or policies are determined by attempting to maximize a certain conception of the good, construed as human welfare (see Consequentialism; Welfare).

Particularly when an agent’s preferences are formed by social or political processes that seem unjust (for example, practices such as slavery, or institutional discrimination), some theorists have argued that the agent’s preferences may have a content that we can evaluate as violating reason. Such an evaluation requires a non-instrumental moral reasoning procedure that determines not only the content of the preferences a rational agent ought to have, but also the ways in which such preferences are rightly formed.

Even if practical reason is the source of normatively authoritative directives (or imperatives) governing our conduct, philosophers disagree about whether these directives can (solely by virtue of that authority) motivate us to act (see Moral motivation). Hume argues that reason is motivationally inert, so that only our passions can motivate us. Reason, according to Hume, is a mere slave to our passions that never itself defines or precipitates action directly.

In contrast, Kant insists that his ‘moral law’ can move us to action, and this belief in the motivational efficacy of practical reason arises in part from his concern to show that, no matter what our interests, desires or emotions, each of us as a rational being always has the capacity not only to understand what the moral course of action is, but also to perform that action, by virtue of the fact that our reason is always in a position to comprehend and initiate appropriate moral conduct.

However, there is a related issue about how to describe cases where passion or desire seemingly leads us to act against our ‘better judgment’. There has long been controversy about how to conceive such irrational ‘weakness of will’ and even about whether the idea of such weakness is really logically coherent (see Akrasia). But it is not surprising that philosophers and others who disagree about the foundations and content of practical reason should in this way (and others) also disagree about the nature and forms of human irrationality.

Ravaisson-Mollien, Jean-Gaspard Félix Lacher (1813-1900)

Félix Ravaisson was a French philosopher, born in Namur. Apart from his three main works - Rapport sur la philosophie en France au dix-neuvième siècle (Report on Philosophy in France in the Nineteenth Century) (1863), Métaphysique d'Aristote (Metaphysics of Aristotle) (1837, 1846) and De l'habitude (On Habit) (1838) - his ideas can mainly be found in articles, fragments and short passages, such as those collected in Testament philosophique (Philosophical Testament) (1901) or others that are still unpublished. None the less, Henri-Louis Bergson, who succeeded him at the Academy of Moral and Political Sciences, according to custom gave a synthetic account of Ravaisson's work, in his Notice sur la vie et les oeuvres de M. Félix Ravaisson-Mollien (Account of the Life and Works of Mr Félix Ravaisson-Mollien) (1934). Bergson insisted on the importance of artistic research in Ravaisson's thought, and one can indeed explain his philosophy as beginning from a meditation on works of art and on beauty. The importance of this starting point can be seen in the privileged role he gives to synthesis in all explanation, for in an artistic masterpiece, it is the whole that allows for comprehension of the parts. Ravaisson gave this idea a metaphysical dimension.

In 1832 Ravaisson was awarded a prize by the Academy of Moral and Political Sciences in a competition on the study of Aristotle's metaphysics. The first volume of his *Essai sur la métaphysique d'Aristote (On Aristotle's Metaphysics)* appeared in 1837, the second in 1846. In 1838 he defended his doctoral thesis, *De l'habitude (On Habit)*. However, Ravaisson never became a professor of philosophy. In 1839 he was made Inspector of Libraries, and fifteen years later he became Inspector General of Higher Education. In 1852, the Minister of Public Education considered the issue of the teaching of drawing in schools. Ravaisson was chairman on the commission set up to report to the minister, while Delacroix and Ingres were among its members. In 1863, at the request of the government, Ravaisson wrote a *Rapport sur la philosophie en France au dix-neuvième siècle (Report on Philosophy in France in the Nineteenth Century)*, which exercised an important influence on academic philosophy. In 1893 he put forward an overview of his philosophy in an article titled 'Métaphysique et morale' (Metaphysics and Morals), which appeared as the introduction to the philosophical journal of that name. A complete exposition of his doctrine appeared in the unpublished fragments put together after his death under the title *Testament philosophique (Philosophical Testament)* (1901).

Ravaisson's most original work is *De l'habitude*, in which, according to Bergson, he broadly sets out a philosophy of nature. He refused to limit habit to its negative aspect, claiming, indeed, that it allows the mind to liberate itself more easily from nature. Nature, according to Ravaisson, is essentially spontaneity. Just as habit is voluntarily acquired, and spirit is thereby made nature, so freedom makes itself into necessity.

Ravaisson also developed a personal conception of the teaching of drawing. In his research on the Venus de Milo, he emphasized the spiritual significance of a pose that expresses love and peace. Finding the paradigm of all the stages of thought in aesthetic intuition, Ravaisson believed that the method goes back to Aristotle in his attempt to make teleological explanation the basis for all true understanding. Indeed, in his studies on the metaphysics of Aristotle, Ravaisson insisted on the fact that Aristotle saw philosophy as a bringing to completion of reality. According to Ravaisson, the essential claim in Aristotle's philosophy is that attention must be focused on the individual, and not dispersed in the general. Philosophy must not stay in the abstract, which is why Aristotle finds the highest truth in the contemplation of works of art.

Rapport sur la philosophie en France au dix-neuvième siècle gives the most complete account of Ravaisson's thought. Having distinguished the mechanical and organic modes of apprehension, he returns to the origin of things, and claims that God created the universe by a process of 'condescension' and love in a way that resembles the creation of art.

Ravaisson begins the *Rapport* by examining the ancient philosophers, and shows that Aristotle is the founder of metaphysics. After a rapid overview of pre-nineteenth-century thinkers, he summarizes the eclecticism of Victor Cousin and insists on his debt to Schelling. His examination of Comte suggests that Comte passed from physical to moral positivism, and, from the same point of view, his study of Paul Janet's works leads him to conclude that true materialism is impossible.

The *Rapport* ends with the examination of two works that seem best to express Ravaisson's fundamental ideas: those of Anthelme-Edouard Chaignet and Jean-Charles Leveque on the theory of beauty. In commenting on them, he shows that beauty, charm and grace spring from souls that are capable of goodness and love. These qualities are the essential driving forces of the world, and as a result the realm of the aesthetic blends with that of philosophy. In short, while materialism finds its origins in the mathematical and physical sciences, living things reveal the spiritual, or rather the moral and aesthetic order, being dominated more by considerations of the order and harmony of the whole than by the detail of its parts; they are more concerned with form than with content. According to Ravaisson, this leaves two main routes for philosophy: analysis and synthesis. The perspective of synthesis is essentially that of art, which consists primarily of composition and construction, and thus also of science, when it is inventive. In other words, synthesis is the main method of philosophy. We judge the whole against the model of perfection which we carry in ourselves. Synthesis strives to explain everything through the absolute perfection that nothing limits; it strives by degrees towards the infinite. Similarly, in the order of wisdom, the wise man freely chooses the good. This also leads to a reconciliation of spirit and nature, which is one way of linking the classical belief that Eros was the first of all the gods with the Christian dictum, 'God is love'.

Testament philosophique repeats the essential themes of the *Rapport*. Ravaisson once more shows the importance of the role of feeling in the search for truth and restates the claim that beauty can only be created where there is enthusiasm. He underlines the values of generosity and love as the proper foundation of education and social morality. In addition to these claims, Ravaisson adds one for a natural belief in immortality.

Translated from the French by Robert Stern
PIERRETTE BONET

List of works

Ravaisson, F. (1837) *Essai sur la Métaphysique d'Aristote (On Aristotle's Metaphysics)*, vol. 1, Paris: Imprimerie royale; vol. 2, Paris, de Joubert, 1846; vol. 1, repr. 1963, Hildesheim: Georg Olms Verlagsbuchandlung. (Ravaisson here criticizes the philosophy of Aristotle, because he sees it as analytic philosophy, while he himself sought a synthetic position.)

Ravaisson, F. (1838) *De l'habitude (On Habit)*, Paris: H. Fournier; repr. in *Revue de métaphysique et de morale*, (2), 1-35, 1894; and as *De l'habitude*, with intro. by J. Baruzi, Paris: Alcan, 1933; repr. Paris: Vrin, 1981. (Ravaisson posits that habit is not simply a negative force, but allows the mind to free itself. In this way free will can be seen as part of the spontaneity of nature.)

Ravaisson, F. (1863) *La philosophie en France au dix-neuvième siècle*, Paris: Imprimerie impériale.(Ravaisson shows that French nineteenth-century philosophy consists of two schools of thought - materialism and spiritualism - and concludes his work with the triumph of the latter, the philosophy of spirit. This work is often referred to as the *Rapport* after some later editions, entitled *Rapport sur la philosophie en France au dix-neuvième siècle*.)

Ravaisson, F. (1893) 'Métaphysique et morale' (Metaphysics and Morals), introduction to *Revue de métaphysique et de morale*.(Overview of Ravaisson's philosophy, in which he claims that metaphysical truth transcends conventional thought processes and that it is necessary 'to love in order to understand'.)

Ravaisson, F. (1901) *Testament philosophique*, ed. X. Léon, in *Revue de métaphysique et de morale*, 1-31.(This work consolidates the fragments of Ravaisson's thought and brings to light the philosophical importance of free will, emotion and love.)

Ravaisson, F. (1933) *Testament philosophique et fragments*, revised and presented by C. Devivaise, Paris: Boivin. (Revised edition of *Testament philosophique* (1901).)

Ravaisson, F. (1953) *Essai sur la métaphysique d'Aristote, fragments du tome III (Héllénisme, Judaisme, Christianisme)*, ed. C. Devivaise, Paris: Vrin.(Ravaisson's unfinished third volume on Aristotle, posthumously assembled from manuscripts.)

(1861) *La science du beau étudiée dans ses principles, dans ses applications et dans son histoire*, Paris, 2 vols.(Dissatisfied by theories in which beauty consists in proportion, Lévêque rediscovers the principles of order and strength through the works of Malebranche and Leibniz. He gives a precise definition of what beauty consists in: it is greatness tempered by order, and expresses strength and will.)

Rawls, John (1921-)

Rawls' main work, A Theory of Justice (1971), presents a liberal, egalitarian, moral conception - 'justice as fairness' - designed to explicate and justify the institutions of a constitutional democracy. The two principles of justice outlined in this text affirm the priority of equal basic liberties over other political concerns, and require fair opportunities for all citizens, directing that inequalities in wealth and social positions maximally benefit the least advantaged. Rawls develops the idea of an impartial social contract to justify these principles: Free persons, equally situated and ignorant of their historical circumstances, would rationally agree to them in order to secure their equal status and independence, and to pursue freely their conceptions of the good.

In Political Liberalism (1993), his other major text, Rawls revises his original argument for justice as fairness to make it more compatible with the pluralism of liberalism. He argues that, assuming that different philosophical, religious and ethical views are inevitable in liberal society, the most reasonable basis for social unity is a public conception of justice based in shared moral ideas, including citizens' common comception of themselves as free and equal moral persons. The stability of this public conception of justice is provided by an overlapping consensus; all the reasonable comprehensible philosophical, religious and ethical views can endorse it, each for their own specific reasons.

1 Justice as fairness

Rawls' overriding aim is 'to provide the most appropriate moral basis for a democratic society' (1971: viii). Despite its many strengths, he sees the dominant utilitarian tradition as providing deficient foundations for democracy. Rawls begins with a normative conception of persons, whom he describes as free, equal, rational and endowed with a moral capacity for a sense of justice. Because of differences in knowledge and situations, free persons inevitably will develop different conceptions of the good. To pursue their good, they make conflicting claims on scarce resources. Principles of justice regulate the division of benefits and burdens resulting from social cooperation. Rawls contends that the appropriate way to decide principles for a democratic society is by conjecturing what principles free persons would agree to among themselves to regulate basic social institutions (the political constitution, property, markets and the family). But to ensure this agreement is fair, they must abstract knowledge of their own situations - of their talents and social positions and their conceptions of the good. Since these principles will be used to assess the justice of existing institutions and the reasonableness of existing desires and claims, Rawls further envisages that contracting parties abstract not just awareness of their own, but everyone's historical circumstances, desires and conceptions of the good. They are to be placed behind a thick 'veil of ignorance'. What such free individuals do know are general social, economic, psychological, and physical theories of all kinds. They also know there are certain all-purpose means that are essential to achieving their good, whatever it might be. These 'primary social goods' are rights and liberties, powers and opportunities, income and wealth, and the basis of self-respect.

The effect of these restrictions on knowledge is to render Rawls' parties strictly equal. This enables Rawls to carry to the limit the intuitive idea of the democratic social contract tradition: that justice is what could, or would, be agreed to among free persons from a position of equality (see Contractarianism). Rawls sees his strong equality condition, along with other moral conditions on agreement (that principles be universal, general, publicly known, final, and so on), as reasonable restrictions on arguments for principles of justice for the basic structure of society. These conditions define the 'original position', the perspective from which rational agents are to unanimously agree. Parties to the original position are presented with a list of all known feasible conceptions of justice and consider them in pairwise comparisons. The parties are rational, in that all utilize effective means to secure their ends, and are motivated by their interests, and so are moved to acquire an adequate share of the primary social goods needed to pursue their interests. The parties are also assumed to be rationally prudent (with zero time-preference), mutually disinterested (of limited altruism) and without envy.

Given these conditions, Rawls argues that the parties would unanimously agree to justice as fairness over the classical and average principles of utility, perfectionist and intuitionistic conceptions, and rational egoism. Its main principles state: (1) each person has an equal right to a fully adequate scheme of equal basic liberties, compatible with a similar scheme of liberties for all; and (2) social and economic inequalities must be attached to offices and

positions open to all under conditions of fair equality of opportunity and must be to the greatest benefit of the least advantaged members of society (the ‘difference principle’). The basic liberties of the first principle are liberty of conscience, freedom of thought, equal political rights, freedom of association, freedoms specified to maintain the liberty and integrity of the person (including rights to personal property), and the rights and liberties covered by the rule of law. These liberties are basic in that they have priority over the difference principle; their equality cannot be infringed, even if inequalities would increase the opportunities or wealth of those least advantaged. Moreover, the rights implied by both principles have priority over all other social values: they cannot be infringed or traded for the sake of efficiency, others’ likes and dislikes or perfectionist values of culture.

Rawls’ argument for these principles is that, given complete ignorance of everyone’s position, it would be irrational to jeopardize one’s good to gain whatever marginal advantages might be promised by other alternatives. For included in one’s conception of the good are the religious and philosophical convictions and ethical ways of life that give one’s existence meaning. It is fundamentally irrational, Rawls contends, to gamble with these given complete ignorance of risks and probabilities. In his later work, Rawls contends that parties in the original position are also moved by ‘higher-order interests’ to develop and exercise the ‘moral powers’ that enable them to engage in social cooperation - the capacity to form, revise and rationally pursue a conception of the good, and the capacity to understand, apply and act from a sense of justice. Parties agree on the two principles underlying justice as fairness since they provide each with primary goods adequate to realize these powers; other alternatives jeopardize these conditions.

One objection to Rawls’ theory is that the parties’ ‘maximin’ strategy of choice is too conservative. Harsanyi (1982) contends that Rawls’ parties should assume an equal probability of being any member in society. Given sympathetic identification with each person’s interests, they should choose (as if they were following) the principle of average utility (see Utilitarianism). But Harsanyi’s ideal chooser, although ignorant of their own identity, still has full knowledge of everyone’s desires and situations; Harsanyi views such knowledge as necessary for sympathetic identification. But Rawls’ parties are without knowledge of anyone’s desires and circumstances, and thus are rendered incapable of sympathetic identification, as well as making interpersonal comparisons of utility. Rawls also finds that, especially under conditions of radical uncertainty, gambling freedom to practise one’s conscientious convictions against added resources betrays a failure to understand what it is to have a conception of the good. For these and other reasons Rawls contends that it is difficult to see how the argument for average utility can arise from his original position. More important, assuming publicity of basic principles, a utilitarian society will not command the willing allegiance of everyone (especially those made worse off), and so will not evince stability (see §3). That basic political principles be publicly known is required by democratic freedom; otherwise citizens are under illusions about the bases of their social relations and are manipulated by forces placed beyond their control. With Rawls’ liberal egalitarian principles, nothing is, nor need be, hidden from public view in order to maintain social stability.

2 Democratic institutions

For Rawls the role of democratic legislation is not to register citizens’ unconstrained preferences and let majority preferences rule, but to advance the interests of all citizens, so that each has the status of equal citizen, is suitably independent and can freely pursue a good consistent with justice. The two principles of justice as fairness designate a common good that provides the end of democratic legislation. Ideally it should not be individual or group interests voting, but citizens and legislators, whose judgments are based on laws that best realize the common good of justice, as defined by the two principles. These principles imply a liberal constitution that specifies basic liberties immune from majority infringement. The first principle also requires maintaining the fair value of each citizen’s political rights, thereby establishing a limit on inequalities in wealth allowable by the difference principle. The second principle, the ‘difference principle’, preserves the ‘fair value’ of the remaining basic liberties. It suggests a criterion for deciding the basic minimum of resources each citizen needs to fairly and effectively exercise the basic liberties: property and economic institutions are to be so designed that those least advantaged have resources exceeding what the worst off would acquire under any alternative economic scheme (consistent with the first principle). This implies (depending on historical conditions) either a property-owning democracy (with widespread private ownership of the means of production) or liberal socialism. In either case, Rawls assumes markets are needed for efficient *allocation* of factors of production; but use of markets for *distribution* of output is constrained by the difference principle. Whatever effect redistributions from the market

have on allocative efficiency is not a problem for Rawls, since justice has priority over efficiency. The end of justice is not to maximize productive output whatever the distributive effects, any more than it is to maximize aggregate utility (see Justice §5).

3 Stability

The argument from the original position aims to show that justice as fairness best coheres with our considered judgments of justice (in 'reflective equilibrium'). But why should we care about justice enough to allow its requirements to outweigh our other aims? Stability addresses this issue of motivation. A conception of justice is 'stable' whenever departures from it call into play forces within a just system that tend to restore the arrangement. Unstable conceptions are utopian, not realistic possibilities. Hobbes argued that stability required a nearly absolute sovereign. This is incompatible with Rawls' democratic aim. To argue that justice as fairness is stable, Rawls appeals to principles of moral psychology to show how citizens in a 'well-ordered society' can acquire a settled disposition to act on and from the principles of justice. He then argues that justice as fairness is compatible with human nature, and is even 'congruent' with citizens' good in a society well-ordered by justice as fairness.

A person's good is the plan of life they would rationally choose based on their considered interests from an informed position of 'deliberative rationality'. Rawls' congruence argument contends that it is rational, part of a person's good, to be just and reasonable for their own sake in a well-ordered society. Assuming citizens there have a sense of justice, it is instrumentally rational for them to cultivate this capacity by doing justice, in order to achieve the benefits of social cooperation. On the Kantian interpretation of justice as fairness, the capacity for justice is among the powers that define our nature as rational agents; by developing and exercising this power for its own sake, citizens realize their nature and achieve moral autonomy. The Aristotelian principle is a psychological law which implies that it is rational to want to develop the higher capacities implicit in one's nature. Since the circumstances of a well-ordered society describe optimal conditions for exercising one's sense of justice, it is rational to want to cultivate the virtue of justice for its own sake and achieve moral autonomy. Justice and moral autonomy are then intrinsic and supreme goods in a well-ordered society, so the Right and the Good are 'congruent'. If so, it is not rational to depart from justice, and a well-ordered society manifests inherent stability.

Hegel argued that Rousseau's social contract, like Hobbes', was individualistic and incompatible with the values of community. Contemporary communitarians (for example, Sandel 1982) re-state Hegel's criticism, contending that Rawls' original position presupposes abstract individualism, with a metaphysical conception of persons as essentially devoid of the final ends and commitments that constitute their identity (see Community and communitarianism). In *Political Liberalism* (1993) Rawls contends that this is mistaken. In *A Theory of Justice* he presupposes, not a metaphysical conception of persons, but a practical account of the conditions of political agency, as grounded in the moral powers. Given congruence, maintaining justice and just institutions is the shared good that underwrites the values of community (or 'social union') among free and equal moral persons.

Rawls' Kantian congruence argument addresses the classical aim of showing how justice can be compatible with the human good. It is one of Rawls' most original contributions to moral philosophy. It also bears implications that led Rawls subsequently to revise his view.

4 Political liberalism

The problem with congruence is that it conflicts with the 'reasonable pluralism' of liberal societies, which should tolerate a wide range of religious, philosophical and moral views. The 'burdens of judgment' imply certain limitations on judgment, so that under free institutions we cannot expect agreement upon a comprehensive metaphysical, religious, or moral doctrine or conception of the good. But congruence implies that widespread acceptance of the intrinsic good of moral autonomy is a condition of liberal stability. By hypothesis, most conceptions of the good in a well-ordered society can endorse Rawls' principles of justice. The problem is, some may not accept the intrinsic goodness of moral autonomy. Teleological views, such as liberal Thomism or a reasonable utilitarianism, will gain adherents in a well-ordered society, and for these views justice and autonomy are at best but instrumental to the one rational and intrinsic good (the Vision of God, and aggregate or average utility, respectively). The incompatibility of congruence with reasonable pluralism then undermines Rawls' original argument for stability.

In *Political Liberalism* Rawls reformulates the justification of justice as fairness as a 'freestanding' political conception. He aims to provide a public justification for justice as fairness acceptable to all citizens of a well-ordered democracy. This requires an argument that is not grounded in Kant's or some other comprehensive ethical doctrine, but rather in certain fundamental intuitive ideas implicit in democratic culture. Rawls argues that the features of the original position can be construed as a 'procedural representation' of the idea of social cooperation among free and equal citizens implicit in a democracy. The principles of justice can then be represented as 'constructed' from a 'model conception' of democratic citizens as free, equal and possessed of the two moral powers that enable them to participate in social cooperation. These principles are politically justified since they are presented, not as true, but as most reasonable; they fit best with the considered political convictions of justice shared by democratic citizens, at all levels of generality, in wide reflective equilibrium (see Liberalism §5).

To complete this freestanding political justification, however, Rawls needs an alternative stability argument, one that, unlike congruence, does not rely upon premises peculiar to Kant's moral philosophy. The idea of 'overlapping consensus' says that the conception of justice that is politically justified as reasonable on grounds of individuals' shared conception of themselves as democratic citizens, will also be judged most reasonable or true on independent grounds, specific to each of the reasonable comprehensive doctrines gaining adherents in a well-ordered society. For its own particular reasons, each comprehensive view (for example, Kantians, utilitarians, pluralists, and religions accepting a doctrine of free faith) can endorse justice as fairness as true or reasonable. Justice as fairness then has one public, but many non-public, justifications in a well-ordered society. Assuming an overlapping consensus of reasonable comprehensive views exists there, justice as fairness evinces willing compliance, and hence stability.

Realism and antirealism

The basic idea of realism is that the kinds of thing which exist, and what they are like, are independent of us and the way in which we find out about them; antirealism denies this. Most people find it natural to be realists with respect to physical facts: how many planets there are in the solar system does not depend on how many we think there are, or would like there to be, or how we investigate them; likewise, whether electrons exist or not depends on the facts, not on which theory we favour. However, it seems natural to be antirealist about humour: something's being funny is very much a matter of whether we find it funny, and the idea that something might really be funny even though nobody ever felt any inclination to laugh at it seems barely comprehensible. The saying that 'beauty is in the eye of the beholder' is a popular expression of antirealism in aesthetics. An obviously controversial example is that of moral values; some maintain that they are real (or 'objective'), others that they have no existence apart from human feelings and attitudes.

This traditional form of the distinction between realism and its opposite underwent changes during the 1970s and 1980s, largely due to Michael Dummett's proposal that realism and antirealism (the latter term being his own coinage) were more productively understood in terms of two opposed theories of meaning. Thus, a realist is one who would have us understand the meanings of sentences in terms of their truth-conditions (the situations that must obtain if they are to be true); an antirealist holds that those meanings are to be understood by reference to assertability-conditions (the circumstances under which we would be justified in asserting them).

1 Facets of the debate

Realism became a prominent topic in medieval times, when it was opposed to nominalism in the debate concerning whether universals were independent properties of things or if classification was just a matter of how people spoke or thought (see Nominalism). The impetus for the debate in modern times comes from Kant's doctrine that the familiar world is 'empirically real' but 'transcendentally ideal', that is to say a product of our ways of experiencing things, not a collection of things as they are 'in themselves' or independently of us. Kant's 'empirical realism', confusingly, is thus a form of antirealism (see Kant, I. §5).

Closely related is 'internal realism', as represented by Hilary Putnam, according to which something may be real from the standpoint marked out by a particular theoretical framework, while the attempt to ask whether it is real *tout court* without reference to any such framework is dismissed as nonsensical (see Putnam, H. §§7-8). This re-affirms the thesis propounded earlier by Rudolf Carnap, that there are 'internal' and 'external' questions about existence or reality (see Carnap, R. §5). An internal question is asked by someone who has adopted a language of a certain structure and asks the question on that basis. Only philosophers attempt to ask external questions (are there really - independently of the way we speak - physical objects?). But this is either nonsense or a misleading way of asking whether our linguistic framework is well suited to our practical purposes. 'Internal realism', it should be noted, is certainly not a form of realism, since it admits only language- or theory-relative assertions of existence.

By the mid-1980s, largely as a result of the work of Putnam and Dummett, it had become common to formulate the distinction between realism and antirealism in a variety of what are *prima facie* quite different ways. A realist, it was said, thinks of truth in terms of correspondence with fact, whereas an antirealist defines truth 'in epistemic terms', for instance as 'what a well-conducted investigation under ideal circumstances would lead us to believe'. A realist holds that there are, or could be, 'recognition-transcendent facts', whereas an antirealist denies this. Also present was the idea that an antirealist believes that there can be a 'reductive analysis' (see §2 below) of whatever subject matter their antirealism relates to, whereas a realist holds such analysis to be impossible. Seemingly still further from the origins of the distinction, it was said to be characteristic of realism to accept, and of antirealism to deny, the general validity of the law of excluded middle. Yet another version located the basic difference in the respective theories of meaning: a realist gave the meaning of a sentence by specifying its truth-conditions, an antirealist by specifying the conditions under which it could properly be asserted.

To come to terms with this debate, the reader therefore needs an awareness of the interrelations of the many definitions of the realism-antirealism distinction, and of the inexactness of fit between some of them and others.

2 Ontological realism/antirealism

The primary form of the definition deals directly in terms of what really exists. A realist about Xs, for example, maintains that Xs (or facts or states of affairs involving them) exist independently of how anyone thinks or feels about them; whereas an antirealist holds that they are so dependent. We are not speaking here of causal (in)dependence: the fact that there would be no houses if people had not had certain thoughts should not force us into antirealism about houses. So the point of the definition is better brought out by saying that *what it is for an X to exist* does not involve any such factors (whatever their causal role in the production of Xs may be). Nor does the definition entail an antirealist stance towards the mental. Realism about mental states is a *prima facie* plausible option, holding that our mental states are what they are whatever we think they are, or whatever we would come to think they were if we investigated.

Where philosophers have argued for realism about some particular subject matter (for example, universals, ethical value, the entities of scientific theory), one particular argument is repeatedly found. For the subject matter in question, it is claimed, we find that everyone's opinion is the same, or tends to become the same if they investigate, or that (in science) theory seems to 'converge', later theories appearing to account for the partial success of their predecessors. Why should this be, unless it is the effect of a reality independent of us, our opinions and our theorizing? (See Universals; Scientific realism and antirealism.)

In consequence, there are two broad antirealist strategies, both common. One is to argue that the supposed conformity of opinion, actual or potential, does not exist - so we hear of the diversity of ethical or aesthetic judgements, for instance, or the extent to which judgements of colour depend on viewing conditions and the state of the observer. The other is to accept the conformity, but explain it as arising from a uniformity of *our* nature rather than the independent nature of things. Thus it is argued that moral 'objectivity' is really 'inter-subjectivity' - that is, a result of shared human psychological responses rather than of independent moral properties in the world - or that the similarity between different languages' schemes of classification is a product of shared basic human interests, not something forced on us by 'real' universals.

In modern times nobody has made a more radical use of this method of explaining conformity of judgement in terms of intersubjectivity than Kant. He argued that even the experience of our environment as extended in space and time was a human reaction to things that were in themselves not of a spatiotemporal nature, and to which other beings might just as legitimately react altogether differently. In the face of this it may be felt that the argument from conformity is better used to establish a very abstract realism, namely that there must be *something* independent of us, rather than that any specific property or type of thing must be so.

Two other objections have been used against certain forms of realism. One is that the realist provides no account of how the supposed real things or properties can actually have an effect on our experience. What sense do we have, it is asked, that is affected by the ethical properties of the moral realist, or by the real properties of necessity and possibility that the modal realist posits? The common realist practice of speaking of 'intuition' in these contexts is rejected as providing only a word, not an answer. The second type of objection (christened the 'argument from queerness' by John Mackie (1977), who used it in the moral context) claims that the things or properties in which the realist believes would need to be too strange to be credible (see Moral realism; Modal logic, philosophical issues in).

A closely related definition of the realism-antirealism distinction focuses not on the independence of things but on the truth of judgements about them: realism takes truth to be correspondence with fact and our knowledge of truth to be a separate matter, whereas antirealism defines truth 'in epistemic terms', that is to say as what human beings would believe after the best possible application of their cognitive faculties. This is much more a change of perspective than of substance. It is natural to think that if some object exists independently of us, then judging truly must consist in getting our judgement to match the way the object is; while if the object is determined by (perhaps a projection of) our cognitive and/or affective faculties, judging truly can only mean judging as those very faculties lead us to judge.

Harder to assess is the position of *reductive analysis* in the debate. A reductive analysis exists where what makes statements about one kind of thing, *A*, true or false are the facts about another kind *B*. (*A*s are then said to be reducible to *B*s.) Classically, phenomenalism claims that statements about physical objects are thus reducible to statements about sensory experiences; behaviourism holds that propositions about mental states are reducible to ones about dispositions to physical behaviour. Does accepting such a reduction mean accepting antirealism about

the *A*s, while rejecting reduction of *A*-statements mean accepting realism? Some philosophers speak in this way, and there is a clear point to doing so: if a reduction is possible, then a complete statement of everything there ‘really is’ would not need to mention *A*s - it could speak of *B*s instead. Besides, reductive analyses have usually been offered in opposition to a different conception of what *A*s are, and in relation to *that* (rejected) conception of an *A* the reducer is certainly saying that there are no *A*s. But it is not thereby said that *A*s and facts about them are dependent upon us - only that they are really certain sorts of fact about *B*s; our attitude to their independence is therefore a question of whatever we think about the latter (see Reduction, problems of).

3 Epistemological versions

It is common to hear realism characterized in terms of the limits of knowledge as the belief that there are, or could be, ‘recognition-transcendent facts’ (meaning thereby facts which lie beyond *our* cognitive powers - there is no intention to saddle the realist with the view that there may be facts which simply could not be recognized at all). Antirealism then becomes the view that no such facts are possible.

The motivation for this epistemic version of the realism-antirealism divide is not hard to see. If the way something is is independent of the way we are, what could rule out the possibility that there should be facts about it beyond our powers of knowledge? Conversely, if its whole nature is due to the way we ‘construct’ it through our style of experience and investigation, how could there be anything about it that our cognitive faculties cannot recover? Although understandable, this is quick and imprecise. Consider someone who holds that the nature of the physical world is utterly independent of what human beings may believe it to be, but also has such anthropocentric theological inclinations as to hold that God must have given us cognitive powers equal, in principle, to discovering every fact about it. If we call this philosopher an antirealist on these grounds, we have surely changed the original subject, not just drawn it from another perspective.

This brings out the significance of formulating the epistemic criterion in terms of mere possibility (there *could be* recognition-transcendent facts) rather than actuality, thus allowing the philosopher who thinks, for whatever reason, that our cognitive powers are in fact a match for reality, still to be a realist by virtue of accepting that our powers might have been more limited without reality being any different.

It is one thing to suggest that there may be facts beyond our powers of recognition, quite another to hold that this is true of certain specific facts; the former is just modesty about our cognitive capacities, the latter a positive scepticism. So to imply an intrinsic connection between realism and scepticism, as some do, is very different from identifying realism with a belief in the possibility of recognition-transcendent facts.

Again, there is a plausible line of thought linking realism closely to scepticism. If a certain type of fact is as it is quite independently of us, then our knowledge of it must depend on an intermediary, namely the effect that it has upon us. But then we encounter the sceptical argument of which Descartes’ fiction of a malicious demon represents the classic formulation: how are we ever to know that this intermediary effect is produced by the sort of thing we think it is produced by, and not rather by something completely different? Hence, starting with realism, we arrive at scepticism.

However, it seems undesirable to use scepticism (and the absence of it) to characterize the realism-antirealism distinction. The classic argument from realism (as independence of the subject) to scepticism may be a formidable one, but it nevertheless involves substantial assumptions which can be challenged; to adopt terminology which makes it sound as if its conclusion were true by definition invites confusion. Besides, scepticism is not itself a precise notion, and there may be forms of it which apply even under certain antirealist conceptions. For instance, one who thinks that truth is to be understood as the opinion that would be reached under ideal conditions may still be a sceptic, because they remain sceptical of our ability to recognize ideal conditions or know how closely we have approximated to them.

4 Logical and semantic versions

It is often said that realism and antirealism can be distinguished by their attitude towards the law of excluded middle (the logical principle that, given two propositions one of which is the negation of the other, one of them must be true): the realist accepts it, the antirealist does not. Again, we can understand this if we think back to the original characterization of the distinction in terms of what is independently there and what we ‘construct’, what is

the case ‘in itself’ and what is so because of our ways of experiencing (see Intuitionistic logic and antirealism).

For explanatory purposes we may consider the world of literary fiction. Most people will be happy enough with the idea that, in so far as anything can be said to be true of the world of Macbeth, just those things are true which Shakespeare wrote into it. But in that case neither ‘Lady Macbeth had two children’ nor its negation ‘Lady Macbeth did not have two children’ is true, since Shakespeare’s text (we may suppose) does not touch on that question; the law of excluded middle fails in this ‘constructed’ world.

Passing now to a genuinely disputed case, there are those who think that whether a mathematical statement is true is one thing, whether it can be proved quite another; and there are those who think that truth in mathematics can only mean provability. For the latter the law of excluded middle is unsafe. From the fact that not-*p* cannot be proved, it does not follow that *p* can be proved; perhaps neither is provable and hence, on this view of mathematical truth, perhaps neither is true. And anyone who equates truth, in whatever sphere, with verifiability-in-principle by us will be liable to the parallel conclusion: only for those propositions *p* where failure to refute *p* is *ipso facto* to verify *p* may we rely on the law of excluded middle. Where verifying *p* and verifying not-*p* are distinct procedures, excluded middle fails. (It is because they are characteristically distinct when the proposition in question makes some claim about an infinite totality that we hear so much about infinite totalities and the rejection of excluded middle.) This explains why some writers (in particular Dummett) often say that the difference between realist and antirealist lies in the difference between their conceptions of truth (see Antirealism in the philosophy of mathematics; Realism in the philosophy of mathematics).

It can also be seen why it should have become common to express the realism-antirealism opposition as an opposition between theories of meaning, and why philosophers should be found speaking of realist and antirealist semantics. Any theory which ties meaning to verification, which equates the understanding of a sentence with a knowledge of those conditions that would verify it or would justify us in asserting it, promotes the view that we have no other idea of what it is for it to be true than for these conditions to be satisfied. Hence the realism-antirealism debate often exhibits neo-verificationist features; sometimes (especially by Dummett) antirealism is presented as the outcome of Wittgensteinian ideas about meaning, sometimes (especially by Putnam) of the alleged impossibility of explaining how our language could ever come to refer to the mind-independent items that realism posits (see Meaning and verification).

Realism in the philosophy of mathematics

Mathematical realism is the view that the truths of mathematics are objective, which is to say that they are true independently of any human activities, beliefs or capacities. As the realist sees it, mathematics is the study of a body of necessary and unchanging facts, which it is the mathematician's task to discover, not to create. These form the subject matter of mathematical discourse: a mathematical statement is true just in case it accurately describes the mathematical facts.

An important form of mathematical realism is mathematical Platonism, the view that mathematics is about a collection of independently existing mathematical objects. Platonism is to be distinguished from the more general thesis of realism, since the objectivity of mathematical truth does not, at least not obviously, require the existence of distinctively mathematical objects.

Realism is in a fairly clear sense the 'natural' position in the philosophy of mathematics, since ordinary mathematical statements make no explicit reference to human activities, beliefs or capacities. Because of the naturalness of mathematical realism, reasons for embracing antirealism typically stem from perceived problems with realism. These potential problems concern our knowledge of mathematical truth, and the connection between mathematical truth and practice. The antirealist argues that the kinds of objective facts posited by the realist would be inaccessible to us, and would bear no clear relation to the procedures we have for determining the truth of mathematical statements. If this is right, then realism implies that mathematical knowledge is inexplicable. The challenge to the realist is to show that the objectivity of mathematical facts does not conflict with our knowledge of them, and to show in particular how our ordinary proof-procedures can inform us about these facts.

1 Platonism and intuitionism

Platonism, probably the most popular form of realism (and sometimes itself called 'realism'), is the view that mathematics is the study of a collection of distinctively mathematical objects which exist independently of us: numbers, functions, sets, lines and so on. Thus the Platonist takes mathematical discourse at face value: to say that there exists a prime number between seven and twelve is to make a straightforward existential claim; and to say that nine is greater than seven is to make a comparison between two objects. Mathematical objects, on the Platonist account, are abstract; they occupy no particular position in space or time. They are immutable and eternal, which explains the unchanging character of mathematical truth. They are related to one another in essential and also unchanging ways: the fact that nine is greater than seven, for instance, is no mere accident, but is part of the nature of the system of natural numbers.

On the Platonist account, reasoning about mathematical objects is just like reasoning about ordinary concrete objects, in that the objects, and collections of them, are simply 'out there' waiting to be investigated and described. There are of course many more mathematical than concrete objects, and the abstractness of the mathematical objects sets them apart, but they are none the less like concrete objects in their relation to our cognitive processes: in both cases the objects would exist, bearing the properties and relations they currently bear, whether or not we had ever given them any thought. And in both cases, it is reasonable to suppose that there are facts about the objects which we do not yet know, and even facts which we may be incapable of discovering.

At the other end of the realist/antirealist spectrum from Platonism is the position of 'intuitionism', according to which it makes no sense to speak of true-yet-undiscoverable mathematical facts. According to L.E.J. Brouwer, the twentieth century's paradigm intuitionist, our knowledge of mathematical objects is best explained by the view that these objects are actually *created*, not discovered, by us: mathematical objects are the products of human mental activity. As the intuitionist sees it, to say, for instance, that there is a natural number with such-and-such property is to say that we can mentally construct such a number. To say that every natural number has a given property is not to make a claim about some pre-existing infinite collection, but is rather to assert the existence of a particular kind of proof-procedure (see Intuitionism; Constructivism in mathematics).

Reasoning about infinite collections in general is a much more cautious affair under the intuitionist's strictures than under the Platonist's, since the only true universal claims, according to the intuitionist, are those which come with effective proof-procedures. And because the only states of affairs relevant to the truth of mathematical

statements are those given by our own mental constructions, a statement is counted true by the intuitionist just in case it is provable. As a result, the kinds of mathematical reasoning accepted by the intutionist differ from those accepted by the Platonist, and the intuitionist must reject some of the truths of classical mathematics.

Though the original motivation for intuitionism was a view about the creative powers of the human mind, a quite different motivation stems, in the work of Michael Dummett, from general views about the relationship between meaning, truth and verification (see Dummett, M.A.E. §3). As Dummett sees it, to grasp the meaning of a statement is to understand how it is used, and in particular to know what counts as a verification or falsification of it. Since mathematical statements are verified via mathematical proof, the view as applied to mathematics is that the meaning of a mathematical statement is given not in terms of facts which it purportedly represents, but rather in terms of the procedures which would count as a proof of it. Again, the upshot is that truth reduces to provability, and the idea of a realm of independent mathematical facts is rejected as incomprehensible.

The Platonist response to the intuitionist is that the revisionary picture recommended by the latter is under-motivated. Against Dummett, the argument is that we have a perfectly good conception of verification-transcendent truth-conditions, and hence of meaning which is given in terms of objective truth, and independently of provability. With respect to the original intuitionists' conception of mathematical objects, the Platonist's claim is that there is no reason to think of the objects of mathematics as dependent on us, and that the view of the mathematician's activity as one of creation, rather than discovery, does not do justice to this activity. An important complaint made by the Platonist in this regard is that the picture of mathematical objects as mental constructions fails to do justice to the communal nature of mathematical research, since it makes each mathematical object accessible only to its creator.

2 Platonism and epistemology

The strength of the Platonist position is that only the Platonist can hold that the ordinarily-accepted statements of classical mathematics are strictly and literally true. We all want to affirm, in some sense, that there is a prime number between three and six. But having said this, the non-Platonist must add when pressed that the claim is not to be taken quite literally, or is at least not to be taken to have objective truth-conditions. Only the Platonist can say what in weaker moments almost all of us would like to say, which is that there simply *is* a prime number between three and six.

But the literal reading of mathematical discourse does come at a price. Particularly problematic, at least on the face of it, is the explanation of mathematical knowledge. The mathematical objects posited by the Platonist are, unlike concrete objects, entirely divorced from human experience; we cannot perceive them, nor do they bring about any perceptible effects. It is therefore not easy to see how we might be in a position to know anything about them. A central challenge to the Platonist is to show that Platonism does not leave our mathematical knowledge a mystery.

There are two main lines of Platonist response to this epistemological challenge. The first is to claim that we bear a relationship to mathematical objects which is analogous to the perceptual relation we bear to concrete objects: as empirical data are to knowledge of concrete objects, so mathematical intuition is to knowledge of numbers, functions and sets. Such a position is held by Kurt Gödel (1944), who points out that even our knowledge of concrete objects is not direct, but is inferred from immediately evident sensations; so too, on this view, knowledge of mathematical objects is inferred from the immediate knowledge of simple mathematical truths. The primary challenge facing the mathematical-intuition theorist is to give a clear account of the nature of mathematical intuition, and of how, precisely, it relates us to the objects in question.

The second Platonist approach is to argue that knowledge about mathematical objects is simply knowledge of propositions, or perhaps of entire theories, in which those objects figure. The problem of explaining knowledge about the objects is then reduced to the problem of explaining the justification of those propositions or theories. Thus, for instance, Gottlob Frege (1884) holds that knowledge about numbers is simply knowledge of the propositions of arithmetic, which is explained in terms of more general capacities, and not in terms of individual contacts with the objects. An important question facing such an account is whether it is really Platonist; whether, that is, knowledge of propositions of the right form should count as, at bottom, knowledge about objects.

An explanation which attempts to reduce knowledge of mathematical objects to knowledge of entire theories is found in the work of W.V. Quine (1960) and Hilary Putnam (1971). On this account, we know about mathematical

objects in exactly the same way that we know about non-mathematical objects. Consider, for instance, the subatomic particles of modern physics. We know about these things, as Quine sees it, not in virtue of direct contact with them, but rather in virtue of the fact that our best theory includes the claim that these objects exist, and contains specific assertions about them. The evidence for the existence of these objects is just the empirical evidence we have for the truth of the theory as a whole. Similarly for ordinary concrete objects like tables and chairs, on this account: we posit these objects in order to make sense of the brute sensory data before us, and the success of the theory that posits them is the evidence we have that they exist. Given this picture of objectual knowledge, mathematical objects pose no special problem: the claim that there are such objects, and that they have the usual mathematical properties, is an indispensable part of our best theory of the world, since mathematics is an essential part of modern physics. Thus we have just as much reason to believe in the objects of mathematics as we do to believe in the existence of pieces of furniture. Whether such an account is successful will turn largely on the tenability of the holist account of knowledge in general.

An interesting response to such indispensability arguments is the ‘instrumentalist’ position, according to which the usefulness of mathematical statements in science is no evidence of their truth, and hence is no evidence of the existence of mathematical objects. As argued by Hartry Field (1980), the central claim is that the statements of mathematics offer a conservative extension of (say) physics, which is to say that, useful as mathematics is as a tool, it allows us to reach only those conclusions in physics which we would have been able to reach (albeit less efficiently) anyway. On this reading, the ordinary mathematical existence-assertions turn out to be useful but not true. The viability of this project turns on whether the conservativeness result can in fact be demonstrated and whether physics can in fact be reformulated in Field’s ‘nominalistic’ terms.

3 Anti-Platonist realism

A different response to the problems surrounding mathematical objects is to view the apparent object-directedness of mathematical discourse as just a mode of speaking, and not an indication that the truths of mathematics really are about objects. On this picture, mathematics is concerned rather with general features of collections, structures, potential measurements, or some such thing. Just as talk involving such phrases as ‘Emily’s sake’, or ‘the average family’ are easily seen to be rephrasable without the use of these terms, and to be free of commitment to any objects meeting the descriptions, so too statements purportedly about mathematical objects can be rephrased, it is argued, in such a way as to remove any *prima facie* commitment to such objects. As long as the rephrasings have objective truth-conditions which render them true or false independently of our ability to recognize whether or not they obtain, such an account is fully realist, though anti-Platonist.

One example of such a rephrasing is as follows. In recognition of the close connection between arithmetic and cardinality, one might hold that claims apparently about natural numbers can be cashed out as claims about collections and their sizes. Thus, for example, the sentence ‘Every natural number has a successor’ is taken to mean ‘For every possible finite collection, there is a possible collection with one more member’, where the phrase ‘one more’ is itself cashed out without reference to the number one. (The reference to possibility will be required in order for the claim to remain true even if the world happens to be finite.)

A more widely applicable reduction is the ‘structuralist’ account, on which mathematical statements are taken to be either about all collections of entities exhibiting the appropriate structure, or about those abstract structures themselves. Thus, the sentence ‘Every natural number has a successor’ can be taken to mean that for every (possible) collection whose members exhibit the pattern N (which we describe in terms of the successor-like relation S), for each member x of the collection there is a member y of that collection such that $S(x,y)$.

With even these simple examples, a number of important issues arise. The first is that the quantification over ‘possible collections’ may involve ontological commitments at least as strong as the commitment to numbers. Thus despite avoiding a commitment to numbers, one does not by such a strategy obviously obtain ontological parsimony, or avoid the difficulties associated with knowledge about abstract objects. Similarly, the usual ways of cashing out the necessary relations between structures or collections will involve quantification over functions; thus in the attempt to avoid one kind of mathematical object, the analysis is apparently committed immediately to another. On the other hand, such reductionist approaches have the benefit of construing arithmetical knowledge in a way which requires no epistemic relation to particular individuals (such as natural numbers), but only to whole classes of collections or patterns. This is an advantage if general properties of such collections or patterns are in

principle accessible to a priori reflection in a way in which distinguishing properties of individuals are not.

An important question about non-Platonist realism is whether it is coherent. Can one simultaneously maintain that the ordinarily accepted statements of mathematics are indeed true, but that there are no mathematical objects? The difficulty in this position is that it requires one to hold that statements such as ‘There are prime numbers between ten and twenty’ are true, while maintaining that there are no numbers. It is not enough to say that the quoted sentence can be rephrased in a way which apparently avoids mention of numbers. For if the rephrasing simply tells us what it means to say that there are prime numbers between ten and twenty, then its truth implies that there are such numbers. (See Alston (1958).)

It is tempting to try to avoid Platonism by saying that statements such as ‘There are prime numbers between ten and twenty’, and hence ‘There are numbers’ are true in some secondary sense - perhaps true ‘within mathematics’, but that they are not *really* true. But it is not clear whether this can be made sense of, since it is not clear what it is for a mathematical statement to be true in one sense and not in the other. In sum: a successful analysis of mathematical discourse which appears to eliminate reference to and quantification over particular mathematical objects does not by itself establish the claim that mathematical statements are free of commitment to mathematical objects. For all that has been said so far, such an analysis may well be regarded as an account of what it is to be committed to those objects. Whether there is more to Platonism than the acceptance of the objective truth of certain mathematical statements - and hence whether there is sense to be made of a non-Platonist realism - will turn, then, on the answers to some extra-mathematical questions concerning ontological commitment and the nature of objects in general.

Reasons and causes

Imagine being told that someone is doing something for a reason. Perhaps they are reading a spy novel, and we are told that their reason for doing so is that they desire to read something exciting and believe that spy novels are indeed exciting. We then have an explanation of the agent's action in terms of the person's reasons. Those who believe that reasons are causes think that such explanations have two important features. First, they enable us to make sense of what happens. Reading a spy novel is the rational thing for an agent to do if they have that particular desire and belief. Second, such explanations tell us about the causal origins of what happens. They tell us that the desires and beliefs that allow us to make sense of actions cause those actions as well.

The idea that reasons are causes has evident appeal. We ordinarily suppose that our reasons make a difference to what we do. In the case just described, for example, we ordinarily suppose that had the agent had appropriately different desires and beliefs then they would have acted differently: had the person desired to read something romantic instead of exciting, or had the person believed that spy novels are not exciting, a spy novel would not have been chosen. But if what they desire and believe makes a difference to what they do then the desires and beliefs that are those reasons must, it seems, be the cause of the person's actions.

Despite its evident appeal, however, the view that reasons are causes is not without its difficulties. These all arise because of the manifest differences between explanations in terms of reasons and causal explanations.

1 The normative character of reason explanations

If we are told that a person acts because of a desire and belief they have then we have an explanation of their action in terms of their reasons; a rationalization, as it is sometimes called. Those who think that reasons are causes claim that such rationalizations are a kind of causal explanation. This view has evident plausibility, as it allows us to make straightforward sense of the idea that our desires and beliefs make a difference to what we do. If we had had different desires and beliefs then we would have behaved differently because the cause of our behaviour would itself have been different.

Even so, many anti-causalists think that reasons are not causes. One problem, as they see it, is that if reasons were causes then there would have to be underlying causal generalizations connecting desires and beliefs on the one hand, with actions on the other. For causal explanations are derived from, grounded in, such generalizations. However, they argue, rationalizations have a normative aspect which eludes capture in the purely descriptive terms in which causal generalizations deal. No such generalizations can therefore be found. An example will help to make the problem more vivid.

Suppose someone wants to illuminate the room and believes that they can do so by flicking a particular switch. Provided nothing else is wanted, and provided there are no interfering factors that it make it pointless for the person to try to do anything, it follows that they should flick the switch. Flicking the switch would be the rational thing to do, in one perfectly ordinary sense of the term rational; it is what we would expect to happen if we are to make sense of what is going on. However, say the anti-causalists, we cannot go on to conclude that the individual will flick the switch. For that would be to move illicitly from an 'ought' to an 'is'. In this respect, they insist, causal generalizations are therefore quite different from rationalizations. Causal generalizations purport to tell us what will happen without regard to what should. If one billiard ball moves towards another at a certain speed, and if nothing else interferes, then the other ball will move off in a certain direction at a certain speed. Whether or not it should is neither here nor there.

According to these anti-causalists, the fact that rationalizations have a normative aspect means that they serve a quite different function from that of causal explanation. Of course they agree that if, in the case just described, the agent does flick the switch then it will be useful to think of her as having done so for a reason; but they insist that it is a mistake to suppose that we thereby give the cause of what happened, because the function of such a rationalization is to give a useful interpretation of what happened, not a causal explanation. We interpret each other as creatures with desires and beliefs who act in various ways, and so instantiate the various rational norms, because doing so helps us to understand what we have done, are doing, and will do; it helps us to make sense of each other. However these interpretations no more presuppose that our desires and beliefs are states that play a

causal role than do the similar interpretations we give of the behaviour of desktop computers, electronic calculators and telephone exchanges in terms of the desires and beliefs that they possess - or so say these anti-causalists. In each case we simply work with a useful fiction or manner of speaking.

Note that two crucial claims have been made. First, talk of an agent's desires and beliefs is not unlike talk of similar states in electronic calculators and the like, a fiction or manner of speaking. Second, this manner of speaking is useful because it helps us understand what has happened, does happen and will happen. The question is: how are we to put these two claims together? If desire and belief talk is indeed useful then we need to know why this is so, and the most straightforward explanation available is surely that our desires and beliefs causally explain what we do. For then our understanding of what has happened, does happen and will happen is the familiar sort of understanding that comes from knowing about the causal origins of the events in question. On this way of looking at things there is therefore a crucial difference between human beings on the one hand, and electronic calculators, telephone exchanges and the rest on the other. Desire and belief talk really is a mere manner of speaking in the latter case, but not in the former. Electronic calculators and telephone exchanges are like human beings, but not the same as them, for they do not really have desires and beliefs, whereas human beings do. We must therefore ask why anti-causalists resist giving this most straightforward explanation of the usefulness of rationalizations, at least in the case of human beings. Why do they think that all desire and belief talk is a mere manner of speaking?

The answer is that they think the normative character of rationalizations makes it impossible to state rationalizations in the form of causal generalizations. It is, however, difficult to see why they think that this is so. For whenever we explain what someone does by appeal to their reasons we in fact make an additional, descriptive assumption, one which is perfectly suited to turn the normative claim anti-causalists accept into a descriptive causal generalization: namely, the assumption that the agent in question is a rational agent, in the relevant sense of rational. Thus, even though the claim 'If an agent wants to illuminate the room, and believes that they can do so by flicking the switch, and wants nothing else more, and there are no interfering factors present, then the agent should flick the switch' does not look at all like a causal generalization, the claim 'If an agent desires to illuminate the room, and believes that they can do so by flicking the switch, and wants nothing else more, and there are no interfering factors present, and the agent is rational, then they will flick the switch' most certainly does. Seen in this light, being rational is itself a substantive disposition agents possess, a disposition which makes its own difference to what they do.

In conclusion, it seems that anti-causalists are right that rationalizations have a normative aspect, but wrong that we are therefore unable to state them in the form of causal generalizations. We have seen no reason to disagree with the causalist that the usefulness of rationalizations lies in the fact that they offer us causal explanations.

2 The logical connection argument

Anti-causalists have another objection. Hume taught us that cause and effect are logically distinct. Causal generalizations like 'If one billiard ball moves towards another at a certain speed, and if nothing else interferes, then the other ball will move off in a certain direction at a certain speed' thus report substantive facts about the world. This is because, logically speaking, we can imagine the cause with an entirely different effect, or without any effect at all. The second billiard ball might have gone in any of a number of different directions, or disappeared, or stayed precisely where it was (see Causation).

However, anti-causalists point out, in the generalizations causalists suppose ground our rationalizations the so-called cause and effect are not logically distinct. The claim 'If someone wants to illuminate the room, and believes that they can do so by flicking the switch, and wants nothing else more, and nothing else interferes, and the person is rational, then they will flick the switch' does not report a substantive fact about the world because, if the agent is indeed rational, we cannot imagine these desires and beliefs having different effects. Imagining them with different effects - imagining the agent doing something different - is to imagine an agent with different desires and beliefs. The generalization linking desires and beliefs on the one hand, and doings on the other, unlike the claim linking the separate movements of billiard balls, thus reports a logical truth, not a substantive causal generalization.

The key idea behind this logical connection argument, as it is known, is plausible enough. We can indeed define

desires and beliefs as states that occupy certain functional roles: that is, desires and beliefs are states that are caused by various perceptual inputs, and which in turn cause various sorts of behavioural and other mental outputs (see Functionalism). Those who propose the logical connection argument are thus right that the cause and effect in a rationalization are not logically distinct in at least this sense: in describing the cause as a desire - that is, as a state that occupies a certain functional role - we thereby mention events of the effect kind, for we must mention behaviour in characterizing the relevant functional role.

However, if this is right, then it becomes clear that the anti-causal thrust of the logical connection argument is undermined. For the states of an agent that occupy the functional roles characteristic of desire and belief - presumably complex states of an agent's brain - are logically distinct from the behaviour they help to produce. It is our descriptions of these states as states that are occupiers of certain functional roles - that is, as states that, inter alia, cause certain sorts of behaviour - that are logically connected with facts about behaviour, not the states themselves. Even though the generalization connecting desires and beliefs with behaviour is indeed a logical truth, it thus follows that the desires and beliefs themselves - that is, the states that occupy the functional roles characteristic of desire and belief - are still logically distinct from the behaviour that they cause, just as Hume insisted cause and effect should be.

Moreover, despite the fact that there is this sort of logical connection between desires and beliefs and behaviour at the level of description, note that it is still appropriate to cite an agent's desires and beliefs in giving a causal explanation of what they do. In order to see why, consider an analogy. To say that a glass is fragile is similarly to ascribe to it a state with a certain functional role. A fragile glass is one which is in a state that causes it to break when struck in the appropriate circumstances. The generalization 'If a glass is fragile, and it is struck in the appropriate circumstances, and nothing else interferes, then it will break' is thus a logical truth, just like the generalization connecting desires and beliefs with behaviour. However we can still cite the fact that a glass is fragile in giving a causal explanation of its breaking. For we get information about how a glass broke when we learn that it broke because it was fragile. A fragile glass that breaks need not break because it is fragile, after all. (Just imagine that it breaks when we explode a nuclear bomb next to it.) To say that a glass broke because it was fragile thus gives us causal information because it narrows down the possible ways in which the breakage was caused to those that implicate the state of the glass that occupies the functional role characteristic of fragility.

Likewise, even though desires and beliefs are themselves just states that occupy certain functional roles, including the role of producing behaviour, we can still cite the fact that an agent has certain desires and beliefs in giving a causal explanation of what they do. For when someone who, say, desires to illuminate a room and believes that a room can be illuminated by flicking a switch does indeed flick it, they need not flick it because they have those desires and beliefs. (Just imagine that they flick the switch as the result of being hit by a falling chandelier.) To say that the agent flicked the switch because they had these desires and beliefs thus gives us causal information because it narrows down the possible ways in which the flicking of the switch was caused to those that implicate the states of the agent that occupy the functional roles characteristic of desire and belief.

Those who propose the logical connection argument are right that desires and beliefs are logically connected with behaviour, but wrong to draw the conclusion that they are therefore ineligible to be causes of behaviour. Desires and beliefs may not only cause behaviour; they may also be cited in giving causal explanations of behaviour.

3 The problem of wayward causal chains

Suppose we accept that reasons are causes. Do we thereby commit ourselves to the view that it is necessary and sufficient for an agent's having acted for reasons that they had certain desires and beliefs that caused them to behave in the appropriate way, or are we merely committed to the weaker claim that it is a necessary condition? In order to support the fundamental idea mentioned earlier - the idea that our reasons make a difference to what we do - we need only commit ourselves to the weaker claim. The stronger claim is worth considering, however, for it would be a striking victory for the causalist if we could spell out the content of a rationalization in purely causal terms.

There is, however, a well-known objection to this idea. Imagine an actor playing a role that calls for them to shake as if extremely nervous. We can readily suppose that, despite the fact that the actor wants to play the role and believes that it can be done by making certain movements, once they get on stage they are so overwhelmed by

their desire and belief that they are overcome by nerves and rendered totally incapable of action. Instead of playing the role as required, the actor just stands there, shaking nervously. What this case suggests is that it is therefore insufficient for an agent's having acted for a reason that they have desires and beliefs that cause appropriate behaviour. For an agent may well have desires and beliefs that cause such behaviour, and yet, because these states cause that behaviour in the wrong way, as in this case, it would be wrong to say that they act for a reason. In order to give necessary and sufficient conditions for an agent's having acted for a reason in purely causal terms we therefore need to rule out the possibility of such wayward causal chains. In this particular case, we need to rule out the possibility of the agent's desires and beliefs causing them to shake via causing them to become nervous.

Some causalists think that it is plain what is needed. The crucial feature in all such cases, they say, is that the match between what the agent does and the content of her desires and beliefs is entirely accidental. In the case just described, for example, it is entirely an accident that the actor wanted to make just the movements that their nervousness subsequently caused. These causalists therefore suggest that, in order to state a sufficient condition for an agent's having acted for a reason, we need simply to ensure that their behaviour is especially sensitive to the content of their desires and beliefs, as opposed to being sensitive to the operation of wayward factors like nerves. An agent acts for a reason, they suggest, only if, in addition to the other conditions, over a range of desires and beliefs that differ ever so slightly in their content - suppose the actor had desired to act nervously and believed that they could do so making their teeth chatter, or desired to act nervously and believed that they could do so by walking around wringing their hands, they would still have behaved in an appropriate way. This condition is clearly violated in the case described because, no matter what the content of the actor's desires and beliefs, nervousness would still have caused them to shake.

Reasons for belief

Reasons for believing something are one or another kind of ground for believing it. Some grounds provide evidence for a belief; others explain it; some are consciously known, others not. Philosophers are concerned with these and other aspects of reason, including the questions of whether reasons are also causes, whether they yield beliefs only by inference, and whether, by suitable reflection, believers can always become aware of the reasons for a belief they hold.

1 Varieties

To see the several kinds of reasons for believing, consider these examples:

(1) There *is reason* for believing (to believe) that Israeli-Palestinian negotiations will affect the United States' standing in the Middle East.
(2) You seem to be suggesting there is (some) *reason for me* to believe he will not represent us well at the meeting - ah, you are thinking of his previous blunder - I had forgotten.
(3) She *has reason* to believe the referee was unfair.
(4) The *reason why* he believes (the reason for his believing) this myth is not evidential; it is an emotional commitment to his father's views.
(5) Despite the reliable indications that her husband will survive, the only *reason for which* she actually believes this is his saying so, not the favourable statistics.

Case (1) illustrates a normative reason, a reason there *is* to believe the proposition in question (*p*). Such a reason can also be called impersonal, since its status as a reason does not depend on anyone's being aware of it or believing the evidential proposition (the reason): I might have, in the form of propositions I know or believe, the kind of political evidence in question, but the reason could also be merely implicit in what is known by experts. Case (2) illustrates a person-relative normative reason, one there is *for S* (the person in question) to believe. Case (3) exhibits a possessed reason, one *S has*, for believing *p*. In (4) we have an explanatory reason, a reason *why S* believes *p*. And case (5) illustrates a grounding reason, one *for which S* believes *p*. Here, *S* believes *p* on the *basis* of the reason. The belief that *p* thus stands in the (epistemic) basis (or basing) relation to the reason, which is a ground *on account of which S* believes *p*. Such reasons are at least psychological grounds sustaining the belief that *p*, what might be called 'pillars of conviction'. They may also be justifying grounds for *p* itself.

2 Reasons and reason states

Reasons as just described are propositions (conceived as meeting certain conditions, for example being true or believed by *S*). But whereas a proposition *q*, an obvious truth implying *p*, may be a reason there *is* to believe *p* whether or not anyone believes *q* - and thus *q* is in that sense an *external reason* for believing *p* - *q* must be believed by *S* in order to be a reason *for* which *S* believes *p* (case 5). That an accurate thermometer says a child has fever is a reason *to* think so, but this proposition is not a reason *for* which I believe this, until I come to believe the proposition and thereby come to believe the child has fever.

Given that we do not believe *for* reasons until they enter our minds, and given the obvious truth that one belief of *S*'s can be a reason *why S* holds another belief, some philosophers speak of (certain) beliefs themselves as reasons for believing. We can preserve these points, however, and achieve greater clarity, by construing reasons for believing as propositions and using 'reason state' for a belief *expressing* such a reason, in the sense that its content constitutes the reason. Reasons proper, as abstract entities, are presumably not causes. In so far as denials that reasons are causes make this point, they are plausible. But reason states, as concrete psychological elements, are good candidates to be causes (of a certain kind). Granted, a proposition can be cited as a reason why *S* believes *p* (case 4) and this *appears* to attribute causal power to it; but the proposition can *be* a reason why *S* believes *p* only if either its truth, or at least *S*'s believing it, actually explains why *S* believes *p*: these elements, *not* the proposition itself, play the relevant causal role. That the thermometer says the child has fever is the reason *why* I believe so, because it is my *believing* that the thermometer says this that *explains* my belief that the child has fever. A reason why I believe it, such as brain manipulation that implants the belief, could, however, explain why I believe the child has fever, without being a reason *for* anyone's believing this. Explaining reasons need not be reason states.

We can illustrate all five cases of a reason progressively and in relation to the same proposition: that the thermometer says the child has fever is (1) a reason (for anyone) to believe so; (2) a reason for me - but not the child, who is too young to understand thermometers - to believe so; (3) a reason I have to believe so - once I see the mercury above normal; (4) a reason why I believe so - provided the mercury level, as opposed to, say, my feeling the burning forehead, explains my believing so; and (5) a reason for which I believe so, when my belief is *based on* my reading of the thermometer.

3 Pragmatic reasons

Suppose I desperately need a loan and that, to be persuasive, I must believe I deserve it. Some philosophers would say I thereby have a reason for believing I deserve the loan. In one tradition, deriving from Blaise Pascal and William James, this might be considered a reason for believing that I deserve the loan, even though it provides no evidence of desert. On this view, a reason for believing *p* can be a consideration - not necessarily an evidential one - that, in a certain way, makes believing *p* useful. Such non-evidential considerations are perhaps better regarded as reasons to *cause* oneself to believe, and hence reasons for *acting* rather than for believing. These pragmatic reasons regarding belief are not among the kinds discussed below.

4 Dimensions of appraisal

Among the important questions concerning the relation between believing *p* and reasons for believing it are these: Are such reasons *evidential* (providing some degree of justification of *p*), *explanatory* (at least when combined with information implicit in the context of their ascription to *S*), *causal* (in sustaining or producing the belief that *p*), *internal* (in the sense that *S* can, by suitable reflection, become aware of them, as with one's sensations), *conscious* (in being present to awareness), *inferential* (in providing a kind of premise for the belief that *p*), and psychologically *connected* (linked in *S*'s mind to *p*, for example, as evidence for it)? Consider these questions for our five kinds of reasons.

(1) Impersonal normative reasons are evidential: if there is a reason to believe the child has fever, then that reason (the thermometer's indicating fever) provides some evidence for the proposition that the child has fever. Impersonal normative reasons need not be internal. Perhaps, however, they must be *accessible*, in the sense that someone could, by suitable investigation, become aware of them: normally, in speaking of reasons there are for believing *p*, one is referring to what is known or justifiedly believed, or can be discovered or justifiedly believed, for example, by reconsidering the data or searching the literature.
(2) Person-relative normative reasons are evidential at least *for S* (for example, for me as opposed to people lacking the relevant information). Neither these nor impersonal normative reasons need be explanatory, causal, conscious, inferential or psychologically connected; for they require no belief that *p*: I may, for example, never see the thermometer, and thus may have no belief to be explained, conscious or inferential, nor any occasion to connect the normative reason with *p* as, say, good evidence for *p*. (I might be disposed to make this connection if the reason is highlighted in association with *p*; but there can be a reason for me to believe *p* even if no such psychological connection exists.) Person-relative reasons for believing are usually internal and apparently must be accessible: the thermometer's indicating fever is not a reason *for me* if I cannot become aware of that reading.
(3) Possessed reasons may be normative, as where there is an evidential reason for believing *p, and* one acquires it; they can also be explanatory and causal; and they apparently must be internal. If they are internal, then although they need not be *in* consciousness and in that sense conscious, they cannot be unconscious in the sense that only external help, such as testimony from others, can bring them to *S*'s awareness. But reasons one has can be unconscious in the common sense (associated, for example, with self-deception and buried prejudices) that they are accessible to one only by systematic self-reflection. As to psychological connectedness, perhaps if *S has* a reason for believing *p* and is not merely in possession of information that *is* a reason for believing it, then *S* somehow takes the reason to support *p*. This would not imply a specific belief, say that the reason justifies *p*; one might just see the two in a familiar pattern, like 'If *q* then *p*; and *q*. Hence, *p*'. However, the view that having a reason for believing implies psychological connectedness makes it difficult to explain such self-reproach as 'I had reasons all along to believe it; why did I not see the connections sooner?'
(4) Explanatory reasons for believing are usually possessed and are often, but not necessarily, normative. Arguably, they must be causal. How, without playing some causal role in *S*'s believing *p*, would such reasons explain *why S* believes it? Explanatory reasons can certainly be unconscious; they need not imply any inference -

since manipulation of *S*'s brain could explain why *S* believes *p*; and, as that case also shows, they need not be psychologically connected.

(5) Grounding reasons must be possessed, explanatory and, arguably, causal, internal and psychologically connected. There is better warrant for thinking them connected than for merely possessed reasons, since here *S* believes *p* on the *basis* of the ground. This basis relation is not merely a causal one that might occur as, say, an accidental effect of rays hitting the brain; believing on the basis of a reason implies a response to the reason *as* some kind of support for p. If grounding reasons are connected, however, they still need not be evidential, at least if one can believe for bad reasons *and* such reasons can constitute not just inadequate evidence but none. Grounding reasons are unlike all the others in that they must be inferential, in the broad sense that they exist only if *S* actually believes p on the basis of another belief - a premise belief for *p*. This does not require *drawing* an inference; one can have a grounding reason for *p* either without going through an inferential process or after doing so, and thereby continue to hold the belief that *p* on the basis of the inferential ground in question.

5 Reasons versus grounds

Not all grounds for belief are themselves beliefs. Perceptions, for example seeing blue, are grounds for colour beliefs. Some philosophers call such grounds 'reasons for believing'. These non-inferential reasons can certainly be reasons *why S* believes; but in more perspicuous (and perhaps prevailing) usage, non-inferential grounds for beliefs are not called reasons *for* believing. It may be significant that such grounds are naturally expressible without a 'that'-clause: the reason *why* I believe - what explains my believing - that there is something blue before me is my seeing it, whereas at best I can say that my reason *for* believing this is that I see something blue. This reason is not the perception we started with but a self-ascription of that perception; and offering the reason suggests, misleadingly, that I believe there is something blue before me on the basis of *believing* I see something blue. A further advantage of the stricter terminology is that it allows us to leave open whether some grounds of our beliefs, including justifying grounds, may be external and inaccessible by reflection, as well as to hold that people's reasons for believing (as opposed to reasons why they believe) are always internally accessible to them - which best accords with the plausible idea that, on careful reflection, we can give the reasons for which we actually believe.

Reciprocity

To reciprocate is to return good in proportion to the good one has received, or to retaliate proportionately for harms. The central, contested philosophical issues surrounding reciprocity are whether reciprocity is a fundamental moral principle or a subsidiary one; how we are to measure fittingness and proportionality; and whether the norm of reciprocity requires that we reciprocate for all the goods we receive, or only for the ones we invite. While most philosophers believe that reciprocity is a subsidiary principle which is unproblematic only in the context of fully voluntary transactions, there are significant minority views on this matter.

To some political philosophers, reciprocity appears to be the linchpin of a theory of justice that stands mid-way between an altruistic concern for the welfare of everyone (justice as impartiality) and an egoistic concern for reaping the benefits of cooperation (justice as mutual advantage). On this intermediate view justice involves a commitment to impartial principles that further the welfare of everyone, but only when others have reciprocal commitments. It thus defines a unique conception of justice, distinct from standard utilitarian and contractualist ones (see Justice). Other philosophers, however, see reciprocity as derived from more fundamental moral principles.

Interest in reciprocity as a separate, fundamental principle of social life and morality arose in the twentieth century. Early anthropological studies of gift-giving rituals were developed into comprehensive theories of social exchange, and integrated into structuralist accounts of social life. Stated abstractly, reciprocity appears to social scientists to be a universal social norm, implicated in a wide array of social practices from the most trivial aspects of etiquette to the most lethal aspects of retribution. To evolutionary theorists it seemed plausible to suppose that norms of reciprocity were genetically encoded. Moreover, the development of rational choice theory, and the mathematical manipulation of collective action problems, gave support to the notion that reciprocity (tit-for-tat, beginning with a beneficent opening move) was the best strategy for dealing with (rational) non-cooperative behaviour (see Rational choice theory).

Philosophical efforts to find a rational foundation for morality and justice have often alluded to reciprocity - or at least to related notions such as mutuality and fair play. There are, however, some thorny philosophical issues buried in the concept and practice of reciprocity. One is the question of measurement. In order to reciprocate we need to rank goods (and bads), so as to determine the fitting and proportional response in each case. On the good-for-good side of things, for example, ‘fittingness’ might be determined by what the potential recipients will accept as similar goods. Thus if I make you a gift of a delicacy (say a double chocolate cake) just to delight you, though I do not myself like it or other sweet desserts, you will have to find some other sort of thing - something I do like - if you want to make a fitting return to me. Further, the quantity that will count as a proportional return still needs to be decided, and it is clear that equal money value is not an adequate principle. (I may like emeralds, but giving me the market value of a chocolate cake in emerald chips is a joke, not a reciprocal response.) Besides, the declining marginal utility of money means that an equal market value rule would be oppressive for the poor. Equal marginal sacrifice is a more plausible principle. We could set proportionality to how much the gift ‘costs’ the giver on the margin. Then the reciprocator, if poor, will not ‘suffer’ more from making the return than the giver did, and if rich, will not be able to reciprocate painlessly (unless the gift was painless).

Unfortunately, this rather tidy metric does not look very plausible on the negative side of things (that is, in implementing the policy of returning bad for bad). Victims who want compensation demand plausibly to be made whole; victims who want to exact punishment demand plausibly that the malefactor’s punishment be proportional to the wrongful intent, not to the actual harm done. (People die from negligence as well as from premeditated murder. The harm done is the same; the suffering might even be greater for some victims of negligence.) So the doubts about a coherent account of fittingness and proportionality remain.

Perhaps the deepest philosophical issue raised by reciprocity, however, concerns the scope of the norm. A great deal of the good we receive from others comes to us uninvited and unavoidable. Some of it (like the care of loving parents for their young children) is given to us directly, intentionally. Some of it (like a rich cultural environment) is merely a public good from which we cannot be excluded. The ‘wide’ view of reciprocity holds that the norm covers all of one’s interactions with others; it holds that one owes a fitting and proportional return for all the good

one receives, and not merely for the good actually accepted or invited. The ‘narrow’ view argues that at most we owe a return only for the good we have accepted or invited by voluntary participation in the relevant social practices. On the wide view, reciprocity has important contributions to make to solving general cooperation problems, to giving accounts of obligations to parents, to the state, and to future generations (see Future generations, obligations to; Obligation, political). But even in its narrow form, reciprocity speaks to fundamental issues of justice and fair play.

Recognition

The concept of recognition has played an important role in philosophy since ancient times, when the good life was thought to depend partly on being held in regard by others. Only Hegel, however, made recognition fundamental to his practical philosophy. He claimed that human self-consciousness depends on recognition, and that there are different levels of recognition: legal or moral recognition, and the forms of recognition constituted by love and the state. A similar tripartite distinction can be used to ground a plausible modern account of ethics.

1 The history of recognition

In one way or another the concept of recognition has always played a major role in practical philosophy: in ancient ethics the conviction was predominant that only someone whose conduct met with high regard in the *polis* could lead a good life; Scottish moral philosophy was led by the idea of public recognition or disapproval as a social mechanism through which the individual was motivated to attain the desirable virtues; with Kant the term *Achtung* (respect) eventually takes over the function of a highest moral principle in the sense that it contains the nucleus of the categorical imperative: to treat any other human being only as an 'end in themselves'. None of these authors, however, made the principle of recognition itself the foundation of an ethic; the term was eclipsed by others, regarded as more fundamental. Only Hegel, in this respect a solitary pioneer, used the concept of recognition as a foundation of his practical philosophy.

2 Hegel and recognition

When Hegel undertook the project of reconstructing the development of human morality with the aid of the term recognition, he based it on Fichte's explanation of the possibility of human consciousness of freedom in terms of a theory of recognition: by examining Kant and Schelling on the foundations of natural law, Fichte (1796/7) became convinced that subjects can only achieve consciousness of their freedom if they challenge each other to exercise their autonomy and accordingly recognize each other (and themselves) as free persons (see Autonomy, ethical; Freedom and liberty; Fichte, J.; Hegel, G.; Kant, I.; Schelling, F.; Natural law).

If the idea so outlined was bolstered with elements of Hobbes' and Rousseau's political anthropology, Hegel could use the result as the foundation of his theory of recognition: human self-consciousness depends on the interpersonal experience of being recognized by other human beings (see Hobbes, T.; Rousseau. J.-J.)

For Hegel's purposes, however, the bare assertion of a necessary connection between self-consciousness and interpersonal recognition was not enough. To explain how the experience of recognition could bring about progress in morality, it was necessary in addition to explain the dynamic interrelationship that had to exist between the attainment of self-consciousness and the moral development of whole societies. Hegel's answers to these complex questions form the nucleus of his model of a 'struggle for recognition', according to which moral progress takes place in three different stages of recognition, each of them reached through an interpersonal struggle. Subjects engage in this struggle to confirm their claims to identity.

Peculiar to this approach is a thesis reaching far beyond Fichte, namely the classification into three different types of recognition once the interpersonal basis of self-consciousness had been understood. The mechanism that concedes reciprocally a sphere of individual freedom (which Fichte had in mind in his account of natural law) in fact explains the formation of a subjective consciousness of rights, but by no means does it comprehend the full positive self-understanding of a free person (see Rights).

Hegel therefore adds to legal recognition, which was to include something like what Kant understood as moral respect, two more types of reciprocal recognition which have also to correspond with particular stages of the individual's self-awareness: in love, the subjects recognize each other reciprocally in the unique nature of their desires in order to attain emotional security in the articulation of their desires (see Love). Finally, in the moral environment of the state, a type of recognition unfolds which is to allow the subjects to further their esteem for each other through the very qualities which contribute to the maintenance of social order (see State, the).

In his early works Hegel seems to have been convinced that the transition between these different areas of recognition is characterized by a struggle, conducted among persons in order to be respected in their gradually

growing self-esteem: the claim to be recognized in more and more dimensions of one's own personality leads to an inter-subjective conflict, the solution of which can only be the establishment of yet another sphere of recognition (Honneth 1992: ch. 1).

Hegel is not sociologist enough to think of this process as actually constituting modern societies. Still very much limited by the horizons of German Idealism, he sees it as the totality of the intellectual work which the subjects together have to perform in order to build a common world of the 'objective spirit' (see Idealism).

None the less, Hegel's early model of a struggle for recognition has proved complex enough still to be able to stimulate much present thought in moral philosophy and social theory (Siep 1979; Wildt 1982; Honneth 1992). Yet as early as the *Phänomenologie des Geistes (Phenomenology of Spirit)* (1807) Hegel replaced his initial programme with a concept in which the assumptions of the later system came more and more to fruition; from now on the constitution of social reality is no longer explained through an interpersonal process of conflict-formation, but seen as a result of a dialectic advance of the mind.

However, Hegel's divisions into family, civic society and state in *Grundlinien der Philosophie des Rechts (Philosophy of Right)* (1821) reflect once more the earlier distinction of three types of recognition; and it is this division into three which today allows the development of Hegel's mature system into a practical philosophy (Hardimon 1994).

3 An ethic of recognition

Somewhat as it was for Hegel, today the first step towards a contemporary ethic of recognition is to show that the potential for moral injury arises from the inter-subjectivity of the human form of life: human beings are vulnerable in that specific way we call 'moral', because their identity is constructed out of practical self-awareness which is dependent on the assistance and approval of other human beings from the very beginning (Habermas 1983: 53-67).

If we are to draw a positive idea of morals from this anthropological premise, then the 'moral standpoint' is to be defined by the network of attitudes we have to adopt in order to save other human beings from injuries resulting from the communicative nature of their self-awareness. Positively defined, morality consists of those types of recognition that we are obliged reciprocally to take up if we are to secure together the preconditions of our personal freedom (see Morality and ethics).

Hegel assumed that the differentiation of types of recognition is a matter of which levels of personal self-awareness, or of the human consciousness of freedom, can sensibly be distinguished: for each stage of positive self-awareness on which we have to rely in constructing our autonomy, another type of interpersonal recognition was required, so that the differentiation into family, civil/civic society and state defined three necessary conditions of personal freedom.

If we follow this proposition and detach it from any restriction to particular institutions, a division into three emerges, which appears plausible even today; the three types of recognition then define interpersonal conditions of personal identity as well as moral attitudes, which form together the 'moral point of view': (1) the individual is recognized as someone whose wishes and desires are of unique value to another person; for this type of recognition, which has the character of unquestioning care, the moral philosophical tradition offers terms like 'love' or 'care'; (2) the individual is recognized as a person deserving the same moral responsibility as all others. For this type of recognition, which is characterized by universally equal treatment, the Kantian term 'moral respect' has become established; (3) the individual is recognized as a person whose abilities are of constitutive value to a community; for this type of recognition, which is characterized by special esteem, philosophical tradition lacks adequate moral terms; it may however be appropriate to have recourse here to categories like 'solidarity' or 'loyalty' (see Solidarity).

To specify these three different patterns of recognition in their moral content, and if possible even to interpret them as moral duties, is the task of any theory of morality which aspires to be heir to the Hegelian theory of recognition.

Rectification and remainders

Forgiveness, mercy and gratitude are rectifications, attempts to correct imbalances or set things right between us. Guilt is a moral remainder, a residue acknowledging an unexpiated wrong. Remainders offer us a limited redemption in revealing our appreciation that not everything has been made right.

Forgiveness manifests compassion for wrongdoers, who may or may not deserve it. Questions arise about when, what and whom we can forgive, what forgiving achieves, and when we ought or ought not to forgive. Forgiveness has special value in personal relationships, enabling their renewal. Connections among punishment, repentance, forgiveness and regret (another remainder) are complex, sometimes paradoxical.

Mercy often manifests forgiveness, as in pardons and amnesties. Yet we can also show mercy in administering rules where there has been no wrong. Is mercy unjust? Answers vary according to whether the case resembles a criminal offence or a civil suit. Grounded in others' sufferings rather than their deeds, mercy has us see ourselves in them, but the value of doing so can be qualified by considerations of justice and of self-respect.

Mercy and forgiveness sometimes evoke gratitude, appreciative acknowledgement of another's goodwill. Gratitude can be deserved or misplaced. Debts of gratitude are paradoxical, giving rise to ethical questions. When do we owe more than emotional response? What does reciprocity require between unequals? Some paradoxes may be solved by understanding obligations of gratitude as like those of a trustee rather than those of a debtor.

Guilt is emotional self-punishment (often relievable by forgiveness) which continues even after compensation, restitution or punishment by others. Questions arise about when it is rational and how it is related to shame, remorse, regret and repentance, which are also remainders.

1 Rectification and remainders

Rectification is setting matters right, redressing wrongs, correcting imbalances, settling scores. Remainders are rectificatory feelings that go some way towards morally redeeming us for what we cannot rectify by our actions and sometimes for actions that not even others can rectify.

Apart from punishment, praise and blame, rectificatory actions most explored in philosophy are forgiveness, mercy and gratitude (see Praise and blame; Crime and punishment). Other rectificatory actions - amnesty, apology, compensation, pardon, repentance, restitution and reward - are considered here in terms of their relationships to these three. Because we cannot claim forgiveness, mercy or gratitude as a right, these actions resemble what Kant (1797) called 'imperfect duties', which allow the agent some latitude regarding when, where, towards whom and how much (as in our duty to help others) instead of specifying exactly what must be done (see Kant, I. §10). And yet, as with 'perfect duties', such as the duty to keep a promise, these rectifications can be due specific individuals, who deserve them from us (see Promising). Omissions of gratitude, mercy or forgiveness can make us as vulnerable to moral criticism as failures of honesty, fidelity or integrity. As character traits, ingratitude, being unforgiving and being unmerciful are grave faults, while gratitude, forgiveness and mercy are cherished virtues of the moral life (see Virtues and vices §§2-3).

Ever since Bernard Williams observed that 'moral conflicts are neither systematically avoidable, nor all soluble without remainder' (1965: 179), certain emotional residues have been referred to as 'moral remainders' (see Williams, B.A.O. §5). These include guilt, remorse, regret and sometimes shame, rectificatory responses of feeling rather than action. They reveal relevant positive values of an agent who has acted wrongly or is identified with a bad action or state of affairs. Aristotle said of shame, explaining its status as a 'quasi-virtue', that ideally the occasion for it would not arise, but if it does, we do better to have shame than to be shameless. Remainders can survive rectificatory action as well as hard choices in complex situations where inevitably someone will be wronged and the best we can do is seek the least of evils. Guilt is a paradigm remainder. Other remainders - shame, remorse, regret - are discussed here in terms of their relationships to guilt, and guilt takes us back to rectificatory action.

2 Forgiveness

Forgiveness is a liberal response to those who have wronged us. Like mercy it characteristically (but not

necessarily) manifests compassion for others. It can be offered as a gift, which another may accept or reject. The questions arise when, what and whom we can forgive, what forgiveness does and implies, when we ought to forgive, when it is deserved, when it is a free choice, even when if ever it would be wrong.

We can forgive what we can resent: persons and deeds, wrongs done us and the agents of those wrongs. Hannah Arendt (1958) said we cannot forgive ourselves, that only others can forgive us. Joseph Butler (1726) presented forgiveness as a renunciation of resentment, a view that explains Arendt's observation, as we cannot resent ourselves. Although, like Butler, Arendt emphasizes the liberality of forgiveness, presenting it as letting go of the deed, she also presents it as charitable, claiming that we forgive the offence for the sake of the offender (1958: 241) (see Charity). To forgive is not simply to forget (even if we forget) nor simply to cease resenting with time. It is a choice producing a change of heart from defensive hostility at feeling disrespected or neglected to a friendlier, more pacific attitude of no longer emotionally holding against the offender what we had once resented. It is a natural response to another's sincere apology, expression of contrition, or offer to make amends or atone for an offence.

Forgiveness is of special value in personal relationships (friendships, family, work relationships), where we are most vulnerable to offence, and needs for forgiveness are probably greatest. Arendt called the power to forgive a 'redemption from the predicament of irreversibility' (1958: 237), namely past deeds. Forgiveness enables renewal of relationships but frees us to move on even if we do not renew relations.

Does forgiveness imply at least a willingness to renew relations? In the jointly authored *Mercy and Forgiveness* (1988), Jean Hampton suggests that normally it does, at least with repentant offenders, except when such renewal would be dangerous (as for a battered intimate who rightly believes the offender unregenerate), while Jeffrie Murphy regards renewal as an open question depending on many factors.

If punishment is in question, does forgiveness imply mercy? Arendt called forgiveness and punishment alternative ways of trying to put an end to what is past but also said they are not opposites (1958: 241). Hastings Rashdall (1907) found the two in tension (see Rashdall, H.). Others, including Murphy, find no incompatibility, arguing that punishment need not manifest resentment but may be required out of justice to other offenders and for deterrence to protect the innocent. Mabbott (1939) argued that duties of forgiveness and punishment fall upon different parties. If they are right, forgiveness need not imply total absolution. If it frees one only from the forgiver's resentment and not from the blame of others or the guilt that justifies punishment, it is but a limited redemption of the past's irreversibility.

If then we ought to support punishment of some forgiven offenders, we may also rightly regret that necessity. Such regret is a 'moral remainder'. This example shows, incidentally, that regret does not presuppose that the regretter acted wrongly or was even responsible for what is regretted. Such regret is primarily a sense of loss - here, loss of a permissible opportunity to engage in such otherwise natural manifestations of a forgiving attitude as remitting or not supporting punishment.

Ought we to forgive the unrepentant? Ordinarily, repentant offenders deserve forgiveness. Paradigmatically, a repentant offender apologizes and asks forgiveness, which is then granted, or a victim offers forgiveness, which is accepted and followed by repentance. Yet many find they can forgive the dead who never asked it nor even admitted wrongdoing. We can cease to resent the dead and choose to remember them for their good qualities. Forgiving the dead may be easiest. With the living, problems arise. How can we distinguish forgiving the unrepentant from condoning their offences, tacitly approving them, thus tacitly encouraging their continuation? And if an offender does repent and regenerates, what remains to forgive? Aurel Kolnai (1987) presented these questions as a paradox of forgiveness. Together they suggest that forgiveness is either inappropriate or redundant.

One way to avoid condonation is to withhold forgiveness from the unrepentant. Another may be to combine forgiveness with punishment. What remains to be forgiven even a transformed offender is the offence, for which the offender, however changed, remains responsible.

Are some deeds unforgivably heinous, however deeply repented? Atrocities of slavery and genocide are prime candidates. Survivors and descendants of survivors find the issues complex. Arendt observed that we are unable to forgive what we cannot punish nor can we punish what turns out to be unforgivable (1958: 241). Howard McGary (1992) argues that rational self-interest offers African-Americans powerful reason to move beyond resentment

regarding histories of slavery, advocating such forgiveness (in the liberal sense of letting go) for the sake of the forgiver. Simon Wiesenthal, in *Die Sonnenblume (The Sunflower)* (1969), portrays his dilemma in a concentration camp when a dying, horribly wounded German soldier Karl confessed to having participated in a mass murder of Jews and then begged forgiveness from Wiesenthal as a Jew. Wiesenthal's solution was to listen, appreciate the repentance, even not withdraw his hand when Karl took it but also finally to leave without speaking. Later, upon visiting Karl's mother (under the pretence of having been one of her son's friends), and realizing from what she told him that Karl had been truthful in his account of his early years, Wiesenthal decided not to tell her about Karl's murderous deed. By refraining from this, Wiesenthal granted Karl's wish that his mother be spared disillusionment about her son's honour. Wiesenthal circulated his meditations on these events to respected contemporaries who wrote their reflections, and he published them as a symposium with his essay. Together, they cover most ethical questions that have been asked about forgiveness.

Can forgiveness be wrong? Too ready to forgive, we may be suspected of deficiencies of the self-respect that resentment emerges to defend (see Self-respect). Forgiveness can also be misplaced, as in arrogantly or mistakenly judging that there was anything to forgive. Many of Wiesenthal's symposiasts argued that it would be presumptuous to forgive in the name of others or to forgive an offence done an entire group to which one belongs.

3 Mercy

A natural manifestation of forgiveness in some cases is to mercifully reduce or remit punishment. Mercy is compassionately withholding or mitigating a hardship or penalty that one has authority or power to inflict on another. Leniency and clemency suggest indulgence, softness, mildness. Mercy, however, can issue from strength of character.

Pardons and amnesties can exemplify mercy, although they need not. Pardons remit punishment, or the portion remaining. Ordinarily they are issued after a guilt finding, whereas amnesties preclude such findings. Mercy need not presuppose an offence, however. We can be merciful in administering requirements that can impose hardships and when we can release others from commitments that would impose unforeseen hardships.

The most difficult cases concern mercy for offenders who retributively deserve punishment (what Twambley (1975/6) calls 'the criminal court model') or who deserve to be held liable for compensation or restitution for harm to others (Twambley's 'civil court model') (see Desert and merit).

The criminal court model raises the question whether administrators of the law (or other public systems) can be merciful without being unjust. If one offender is shown mercy, every relevantly similar offender should likewise receive it. But then the reduced penalty has become an offender's right and is no longer merciful. Showing mercy to some and not others on the basis of personal inclinations is unjust favouritism. Reducing penalties for all beyond what justice requires may be unjust to the innocent who depend on deterrence for protection. Thus some philosophers hold that criminals should not be shown mercy by agents of the law (although heads of state may occasionally pardon), and others conclude that mercy for criminals is permissible only when contrary obligations (such as support of a criminal's family) require mitigation of the penalty anyhow.

A satisfactory principle setting out conditions under which offenders deserve mercy would enable administrators to discriminate among offenders without arbitrariness or favouritism. If repentant offenders deserve forgiveness, some may also (or instead) deserve mercy. The desert basis for mercy, however, is not the same. We deserve mercy when we deserve compassion even from those we have wronged or harmed, because of extraordinarily severe undeserved misfortunes in our lives, relative to the lives of our victims and others who depend for protection on enforcement of rules we violated. Such a principle helps distinguish the bases of mercy from the bases of excuse and justification, which rest on facts about the commission of the offence. Excuses remove or reduce responsibility; justifications remove or soften judgments of wrongness (see Responsibility). By contrast, a case for mercy rests primarily on what offenders have suffered, rather than simply on what they have done. It need not cite their offences, although it can, as when the crime recoils upon the perpetrator causing worse suffering than justifiable punishment would have done. The offender's undeserved misfortunes might include such things as having been victimized by yet worse crimes of others or having suffered severe natural disasters. Deserved mercy, so understood, moves towards cosmic moral compensation for inequalities in undeserved misfortune. Such deserved mercy is also a kind of equity and thus a point at which justice and charity come together.

There appears no rightful place for undeserved mercy in criminal court, no way to be merciful to those who do not deserve it without being unjust to other offenders and to the innocent who deserve protection - at least, if the laws are just. Where laws are deeply unjust, judges and juries may be lenient and heads of state issue pardons. Such compassion can respond to both injustice and undeserved misfortune.

On the civil court model (as in Shakespeare's *The Merchant of Venice* (1596/7)), mercy may be permissible or even morally required without being deserved through special misfortune. Just as one had a choice whether to bring a suit, the choices remain whether to call it off or settle. The questions are when such actions are consistent with self-respect and would not condone abuse. As with forgiveness, the offender's evident repentance and apology may obviate the problem of condonation and vindicate one's self-respect. Here mercy is a natural consequence of deserved forgiveness. Yet on the civil as on the criminal court model, offenders who have suffered extraordinary undeserved misfortune may still deserve mercy even if, as unrepentant, they do not deserve forgiveness.

Everyday situations can resemble either criminal or civil court models. Administrative positions allow us discretion in enforcing requirements on others, thus suggesting the criminal court model. Informal relations with friends, neighbours and family suggest the civil court model. In neither is mercy totally arbitrary. It is grounded in the suffering and moral responses of others, calling upon us to see ourselves in them, and it can be restricted by formal justice and by demands of self-respect.

4 Gratitude

Forgiveness and mercy, commonly motivated by compassion for wrongdoers, may evoke gratitude. Gratitude is an appreciative acknowledgement of another's goodwill (or more), often manifesting joy and accompanied normally by dispositions to reciprocate. Fred Berger (1975) argued that gratitude demonstrates that we do not value the beneficiary simply as useful for our own ends. Paradigmatically, gratitude is deserved by a benefactor from a beneficiary who was the intended recipient of the benefactor's freely bestowed (and freely accepted) goodwill. We may be grateful for gifts, favours, support and encouragement, recognition, sympathy, many things others do for us or give us beyond what they owed us or were constrained to offer (see Supererogation).

In an extended (nonmoral) sense, we can be grateful that something occurred, such as good weather, without being grateful to anyone for it. Henry Sidgwick even suggested that gratitude universalized yields the principle that good deeds ought to be rewarded (1874: 279).

Undeserved forgiveness and undeserved mercy can be virtuous, but undeserved gratitude to others is misplaced and suggests deficiencies of respect or self-respect. Gratitude is misplaced when the ostensible benefactor was only refraining from abuse or was compelled to provide the benefit or when the recipient was forced by the donor to accept it. Gratitude is misplaced for 'offers one cannot refuse', as the phrase is used regarding organized crime and likewise for a spouse's refraining from spouse battering. Gratitude for basic decencies is ordinarily misplaced. It risks offending others as well as betraying deficient self-respect.

Deserved gratitude can involve a special obligation, a 'debt' that goes beyond acknowledging appreciation and giving thanks. Richard Brandt (1974) noted that we incur obligations of two kinds, one in undertaking commitments (contracts, promises), the other in accepting benefactions. Ethical questions regarding gratitude tend to be connected with this special incurred obligation: how great the benefit must be to impose a debt, what its measure of value is, how much one should do in return, whether one can ever be done with it, even whether knowingly creating such a debt undermines desert of gratitude.

Is gratitude due one who tries but does not succeed in benefiting us? Some gratitude may be due for good intentions, but what if the would-be benefactor went to some expense or trouble? Do we measure the worth of the deed by what it cost the doer? Or by what it was worth to the recipient? Sidgwick found 'no clear accepted principle' here but noted that if either effort or benefit were great, we tend to feel strong gratitude. Aristotle said that if our relationship to the doer is based on utility, the value to the recipient is what counts, but that in true friendship, the purpose of the doer is what counts (*Nicomachean Ethics* 1163a10-24). What if the value of the effort is high but the benefit meagre, or the donor well-off and the recipient poor? Sidgwick thought that for such discrepancies reciprocating 'something between' is what 'seems to suit our moral taste' (1874: 261).

Do we owe gratitude where need compels us to accept a benefit? Such cases can create mixed feelings, gratitude undermined by humiliation. It is more considerate, as some religions teach, to give alms anonymously. Reciprocity for anonymous giving may be replaced by recipients' dispositions to do likewise for still others.

The idea of a debt of gratitude is paradoxical. Ideally, gratitude expresses gratification. Yet debts are burdensome, and paying them off a relief. Further, how can we owe for a benefit bestowed freely? How can we pay without so transforming the transaction that there is nothing for which to be grateful, and without needing to disguise the relief to avoid offending the benefactor?

These paradoxes arise from the borrower or debtor paradigm of duty or obligation. Borrowers who are granted credit occupy 'inferior' positions in relation to their creditors. Such debtors prove their reliability by paying off the debt, discharging the obligation to the creditor, terminating it. Unpayable debts of gratitude, the fear of which was expressed by Kant in his lecture 'Duties to Oneself' (1780-81), are depressing on this model, as they suggest that one can never adequately prove one's reliability.

The debtor paradigm does not cohere well with obligations of gratitude. A trustee or guardianship paradigm works better. Trustees who accept a deposit owe but are not in debt; they incur obligations but are not 'inferior' and do not have to prove their honour. It can already be an honour to be entrusted. Living up to obligations of a trustee does not terminate them. Terminating trusteeships is what others do when trustees fail to come through.

Accepting a beneficiary's goodwill is more like accepting a deposit (another's good will) than like borrowing. It can be an honour to be so 'indebted', which we express by saying we are happy to be obliged. As the anthropologist Mauss (1967) has shown, entire cultures have been built on the gift relationship, rather than on the economic relationship of buyer and seller.

Thomas Hobbes captured the basic obligation of gratitude in his 'natural law', that '[you are to] suffer him not to be the worse for you, who out of the confidence he had in you, first did you a good turn' and that one should 'endeavour, that the giver shall have no just occasion to repent him of his gift' (1642: 47). Ingratitude, a major moral failing, consists in failing to live up to this basic obligation. More than simple ungratefulness (lack of appreciation, sometimes justified), it gives the benefactor cause for regret.

Gratitude is also among the things for which gratitude is felt, which fits with the observation of Max Scheler that 'love (once it is somehow perceived) evokes a loving response' (1923: 164) (see Scheler, M.F. §7).

5 Guilt

Failure to be forgiving, merciful or even grateful can produce guilt. Unlike guilt for many offences, this guilt cannot be expiated by punishment, because forgiveness, mercy and gratitude cannot be rightfully compelled. Until we are forgiven this guilt may stay as a moral remainder.

'Guilt' is ambiguous between emotional self-punishment for having wronged others (internal guilt; guilt feelings) and the fact or finding of a transgression (objective guilt; a verdict). Internal guilt is associated with the voice of conscience, what Nietzsche (1887) called 'bad conscience' (see Nietzsche, F. §9). The debtor paradigm makes sense of guilt in both senses. Borrowers receive loans, the guilty steal; both are in debt. Borrowers need to demonstrate reliability; the guilty need to reclaim honour. Nietzsche noted that in German '*Schuld*' means both 'guilt' and 'debt'. He speculated that guilt was originally a substitute payment extracted from debtors who defaulted and that this idea was carried into punishment when legal offenders were seen as having defaulted on what they owed society (obedience).

Internal guilt is a 'moral remainder' when it continues after punishment, compensation or restitution, when no more remains to be done to set things right. Removing guilt feelings is a major point of forgiveness. Whether internal guilt is understood as the offender's introjections of victim resentment or, as Nietzsche suggested, as the offender's emotional enactments of introjected victim desires for the compensating pleasure of making the offender suffer, forgiveness naturally cancels the emotional 'debt' by communicating the victim's change of heart. It does not cancel objective verdicts of 'guilty'. Still, if accepted, it removes barriers (internal guilt and victim resentment) to renewals of relationship, barriers that might otherwise remain after punishment.

Are our guilt feelings irrational when they are not based on the belief that we culpably committed an offence?

Herbert Morris (1987) has argued that three kinds of such 'blameless guilt' are not irrational: survivor guilt (or guilt over unjust enrichment, involuntarily benefiting from injustice to others); guilt over acts of one's country or other groups to which one belongs (even though one had no effective say over those acts); and guilt for feelings and desires that one did not act upon. Guilt over unjust enrichment is what we may feel instead of gratitude for benefits made possible by injustice. Here the debtor model of obligation makes sense and suggests a way to alleviate the guilt in some cases. One may feel obliged to use the benefits to help or enrich those treated unjustly, or if that is impossible, to help or enrich their descendants.

Is internal guilt necessary? Neither guilt feelings nor the voice of conscience occur in Aristotle's ethics, although he discussed the fault of *akrasia* (acting contrary to one's better judgment) (see Akrasia). The disposition to feel guilt, as something distinct from shame, may not be learned in all cultures. Ruth Benedict (1946) characterized Japanese culture as a shame culture by contrast with guilt cultures of Europe and North America. Shame is a response to falling short of aims or standards we set ourselves, whereas guilt responds to boundary transgressions (see Piers and Singer 1971; Rawls 1971). Shame is moral when the aim or standard we fail to reach is moral; such shame injures our self-respect (see Moral sentiments §3).

Guilt differs also from remorse, regret and repentance. Repentance is that change of heart whereby a transgressor becomes contrite, remorseful. It is appropriate for major offences. Remorse is intense, often lasting, moral regret regarding our own conduct. Regret, more generally, is sorrow over a fault, offence, mistake or loss, ranging in intensity from mild to deep. It does not presuppose responsibility for what is regretted, although remorse does. More painful than guilt, remorse is emotional gnawing at oneself over one's wrongdoing. Etymologically, it means 'to bite again', suggesting continual reopening of wounds as one rehearses again and again a vivid appreciation of one's wrongdoing. By contrast, internal guilt, as emotional self-flagellation, can actually dull one's appreciation of the wrong. Remorse is often accompanied by shame, and forgiveness removes neither.

Remainders remind us that not everything can be made right, rectified. Yet they offer us a limited redemption in revealing our moral appreciation of that very fact.

Recursion-theoretic hierarchies

In mathematics, a hierarchy is a 'bottom up' system classifying entities of some particular sort, a system defined inductively, starting with a 'basic' class of such entities, with further ('higher') classes of such entities defined in terms of previously defined ('lower') classes. Such a classification reflects complexity in some respect, one entity being less complex than another if it appears 'earlier' ('lower') then that other. Many of the hierarchies studied by logicians construe complexity as complexity of definition, placing such hierarchies within the purview of model theory; but even such notions of complexity are closely tied to species of computational complexity, placing them also in the purview of recursion theory.

1 Hierarchies of formulas

Consider a formal language *L* with quantifiers $\forall$ and $\exists$ (see Formal languages and systems). Let *B* be a class of formulas of *L* such that by adding a $\forall$- or $\exists$-prefix to any member of *B* we get a non-member. We define a hierarchy of formulas of *L* that treats members of *B* as 'basic'. Set $\prod_0^B = \sum_0^B = B$. Suppose that classes $\prod_n^B$ and $\sum_n^B$ have been defined. Let $\prod_{n+1}^B$ = the class of all formulas of *L* of the form $\forall v_1 \ldots \forall v_m \varphi$ for $m \geq 1$, distinct variables $v_1, \ldots, v_m$ and $\varphi \in \sum_n^B$; let $\sum_{n+1}^B$ = the class of all formulas of *L* of the form $\exists v_1 \ldots \exists v_m \varphi$ for $m \geq 1$, distinct variables $v_1, \ldots, v_m$, and $\varphi \in \prod_n^B$. This classifies all formulas of *L* that consist of a string of quantifier-prefixes attached to a member of *B*.

Motivation The complexity of a minimally complex formula (complexity understood as above) defining a given relation may be identified with the complexity of that relation. We can now 'transfer' this hierarchy to a hierarchy of the relations defined by such formulas over an appropriate structure. This was first done by S. Kleene (1943) with first-order formulas over the standard model of arithmetic to get the arithmetical hierarchy.

2 The arithmetical hierarchy

Let L_0 = the first-order language based on function-constants for successor, addition and multiplication, an individual-constant of 0, and a two-place predicate for $<$; variables range over ω. For $\varphi(x_0, \ldots, x_m)$ a formula of L_0 with free-variables among those indicated, φ defines $\{< a_0, \ldots, a_m > \in \omega^m : \varphi(a_0, \ldots, a_m)\}$. A relation *R* is arithmetic iff *R* is defined by some formula of L_0.

Let a formula φ of L_0 be bounded iff each occurrence of $\forall$ in φ is in a context of the form $\forall v$ (if $v < t$ then …) and each occurrence of $\exists$ in φ is in a context of the form $\exists v$ ($v < t$ and …), for *t* a term and *v* a variable; take *B* = the set of bounded formulae, $\prod_n^0 = \prod_n^B, \sum_n^0 = \sum_n^B$. For any *m*, $n \in \omega, m \geq 1$, and any $R \subseteq \omega^m$, we will also let: $R \in \sum_n^0$ iff *R* is defined by some $\sum_n^0$ formula of L_0; $R \in \prod_n^0$ iff *R* is defined by some $\prod_n^0$ formula; $R \in \Delta_n^0$ iff $R \in \sum_n^0 \cap \prod_n^0$. Context should make it clear whether $\sum_n^0$ and $\prod_n^0$ is a set of formulas or a set of relations. This is the arithmetical hierarchy of relations; since any defining formula has an equivalent in prenex form, it classifies all arithmetical relations. It looks like this (with rightward = up):

$$\begin{array}{llllll} & \subset \Sigma_1^0 \subset & \subset \Sigma_2^0 \subset & \subset \Sigma_3^0 \subset & \\ \Sigma_0^0 = \Pi_0^0 = \Delta_0^0 \subset \Delta_1^0 & & \Delta_2^0 & \Delta_3^0 & \Delta_4^0 \cdots \\ & \subset \Pi_1^0 \subset & \subset \Pi_2^0 \subset & \subset \Pi_3^0 \subset & \end{array}$$

Any tuple of natural numbers can be effectively coded by a single natural number; so we lose nothing by restricting the arithmetical hierarchy to reals. The 'arithmetical hierarchy theorem' states that each class contains infinitely many 'new' reals (that is, for each new $n \in \omega \sum_{n+1}^0 - \prod_{n+1}^0$, $\prod_{n+1}^0 - \sum_{n+1}^0$ and $\Delta_{n+1}^0 - (\sum_n^0 \cup \prod_n^0)$ are all non-empty). The definitional complexity of an arithmetic relation is indicated by the class in which it 'first' appears.

This hierarchy is related to classification by recursion-theoretic properties. Most significantly: Δ_1^0 = the class of recursive relations; $\sum_1^0$ = the class of r.e. relations: Δ_2^0 = the class of relations recursive in Post's set *K* (i.e. those of T-degree $\leq 0'$). H. Putnam and Y. Ershov independently proved that Δ_2^0 is also the class of 'trial-and-error' relations: *R* is trial-and-error iff there is a recursive $m+1$- place function *f* such that given any

$\vec{a} =< a_0, \ldots, a_m > f$ guesses forever as to whether $\vec{a} \in R(f(\vec{a}, k) = \text{the kth guess})$, and eventually *f* guesses correctly for ever after. In fact, they found and studied a fine-grained hierarchy within Δ^0_2 (see Putnam 1965).

These facts generalize 'up' the hierarchy. For a real *X*, set $X^{(n+1)}$ = the jump of $X^{(n)}$, with $X^{(0)} = X$. We then have: $X \in \Delta^0_{n+1}$ iff $X \leq_T \{\}^{(n)}$ for $\{\}$ = the empty set; furthermore, $X \in \sum^0_{n+1}$ iff *X* is r.e. relative to $\{\}^{(n)}$. (H. Rogers credits these basic results to Kleene and Post; see Rogers 1967.)

For $R \subseteq \omega^m$ and real *Y*: $R \leq_1 Y$ iff there is a $1-1$ recursive function $f{:}\,\omega^m \rightarrow \omega$ so that for any $\vec{a} \in \omega^m{:}\,\vec{a} \in R$ iff $f(\vec{a}) \in Y$. 1-reducibility (that is, $\leq_1$) is the strongest of the recursion-theoretic reducibilities. For $\mathcal{C}$ a class of relations on ω: *Y* is $\mathcal{C}$-complete iff $Y \in \mathcal{C}$ and for any $R \in \mathcal{C}, \mathcal{R} \leq_\infty \mathcal{Y}$. Fact: $\{\}^{(n)}$ is $\sum^0_n$-complete and $\omega - \{\}^{(n)}$ is $\prod^0_n$-complete for each $n \leq 1$. Let $T_{\sum_n}$ and $T_{\prod_n}$ be the sets of all and only the true $\sum^0_n$ and $\prod^0_n$ sentences respectively. These sets have $\sum^0_n$ and $\prod^0_n$ definitions respectively. (There is no paradox here: 'I am not a true $\sum^0_n$ sentence' requires negation of the truth predicate for $\sum^0_n$, making it $\prod^0_n$ rather that $\sum^0_n$, and thus trivially true!) In fact, these two sets are also $\sum^0_n$-complete and $\prod^0_n$-complete respectively, and thus (by a theorem of J. Myhill) are recursively isomorphic to $\{\}^{(n)}$ and to $\omega - \{\}^{(n)}$ respectively; this expresses the sense in which the jump is the recursion-theoretic analog of $\exists$ in arithmetic, and connects recursion-theory to truth-theory (see Tarski's definition of truth; Semantic paradoxes and theories of truth).

Let us contrast the arithmetical hierarchy with classification of reals by T-degree. Each real has a T-degree; the arithmetical hierarchy only classifies arithmetic reals. In one respect T-degrees are finer than the 'compartments' of the arithmetical hierarchy (that is, $\sum^0_n - \Delta^0_n$ and $\prod^0_n - \Delta^0_n$ for $n > 0$, $\Delta^0_{n+1} - (\sum^0_n \cup \prod^0_n)$ for $n \geq 0$): for example, there are countably many T-degrees with members from $\sum^0_1 - \Delta^0_1$ (see Post's problem in Turing reducibility and Turing degrees). On the other hand, for a real $X \in \sum^0_1$ with $\deg(X) = a, \omega - X \in a$; but if $X \notin \Delta^0_1$ then $\omega - X \notin \sum^0_1$; so except for the T-degree 0 no T-degree is a subset of $\sum^0_1$; similarly for the other compartments of the arithmetical hierarchy. So in another respect these classifications are orthogonal.

3 The analytical hierarchy

Expand L_0 to L_1 by introducing infinitely many predicate- (that is, second-order) variables, allowing $\forall$ and $\exists$ to bind them; without loss of generality let us require them all to be one-place. A relation on ω is analytical iff it is defined by a formula (containing no free predicate-variables), taking each predicate-variable to range over the class of all reals, with individual-variables ranging over ω. ('Analytical' alludes to quantification over reals, as in 'Analysis' in its mathematical sense.)

Now take *B* = the class of formula of L_1 containing no bound predicate-variables and no free individual-variables (though by coding tricks we could restrict *B* further). Set $\sum^1_0 = \sum^B_0, \prod^1_n = \prod^B_0$. For any *m*, $n \in \omega, m \geq 1$, and any $R \subseteq \omega^m$, let: $R \in \sum^1_n$ iff *R* is defined by some $\sum^1_n$ formula of L_1 (with predicate variables ranging as above); $R \in \prod^1_n$ iff *R* is defined by some $\prod^1_n$ formula: $R \in \Delta^1_n$ iff $R \in \sum^1_n \cap \prod^1_n$; again, context disambiguates this double-usage. This is the analytical hierarchy. Using prenexing, it classifies all analytical relations. A picture of this hierarchy with regard to subsethood would look just like that of the arithmetic hierarchy, with superscripts changed from '0' to '1'. Again, each class contains infinitely many new reals, there are $\sum^1_n$-complete and $\prod^1_n$-complete reals, and among those are the truth-set for $\sum^1_n$ and $\prod^1_n$ respectively.

4 Two more hierarchies of relation on ω

Set RA_0 = the set of arithmetic relations on ω. Suppose RA_α has been defined, for α an ordinal. A formula $\varphi(x_0, \ldots, x_m)$ (all free variables first-order and among those shown) defines *R* over RA_α iff for any $\vec{a} \in \omega^m{:}\,\vec{a} \in R$ iff $\varphi(a_0, \ldots, a_m)$, with predicate-variable ranging over RA_α; note this change from §3. Let $RA_{\alpha+1}$ = the set of relations defined by such formulas over RA_α. For a limit ordinal λ: RA_λ = the union of all RA_α for $\alpha < \lambda$. This sequence is the ramified-analytical (hereafter *RA*) hierarchy: 'ramified' because the definitions used allow predicate-variables to range only over entities that were 'previously' defined. Note: if $\alpha \leq \beta$ then $RA_\alpha \subseteq RA_\beta$. This hierarchy is to reals what Gödel's constructible hierarchy is to arbitrary sets (see Constructible universe); indeed work by R. Jensen shows that the latter can be construed as a recursion-theoretic

hierarchy (see Devlin 1973). Note one difference between these hierarchies: the *RA* hierarchy 'peters out' (at the countable ordinal β_0 = least ordinal β such that $RA_{\beta+1} = RA_\beta$). In a natural sense the constructible relations on ω appearing the β_0-stage of the constructible hierarchy extend the *RA* hierarchy; see Odifreddi (1989) for details.

The *RA* hierarchy can be further refined by breaking up each stage $RA_{\alpha+1} - RA_\alpha$ in terms of the quantifier-prefix of the defining formulae (in prenex-form, of course): $\sum^0_{\omega\cdot\alpha+n}$ = the set of relations defined over RA_α by $\sum^1_n$ formulas of L_1; now $\prod^0_{\omega\cdot\alpha+n}$ = the set of relations defined over RA_α by $\prod^1_n$ formulas; $\Delta^0_{\omega\cdot\alpha+n} = \sum^0_{\omega\cdot\alpha+n} \cap \prod^0_{\omega\cdot\alpha+n}$. For $n \geq 1$ we again have a hierarchy theorem: each such class contains infinitely many new reals. There are connections between the *RA* hierarchy, the jump operation, and truth in arithmetic.

An ordinal is recursive if it is order-isomorphic to some recursive well-ordering of natural numbers. There is a countable ordinal ω_1^{CK} = the least non-recursive ordinal ('*CK*' for Church and Kleene, who first studied it). $\omega_1^{CK} < \beta_0$, and if we cut off the *RA* hierarchy at ω_1^{CK} we get the hyperarithmetical (hereafter HA) hierarchy, introduced independently by M. Davis, A. Mostowski and S. Kleene (in Davis 1950, Mostowski 1951, Kleene 1955). For $\alpha = \omega_1^{CK}$, RA_α = the class of hyperarithmetical relations.

The so-called Souslin/Kleene theorem connects the HA hierarchy to the analytical hierarchy: Δ^1_1 = the class of the hyperarithmetic relations; so the HA hierarchy is a classification of the Δ^1_1 relations. Δ^1_1 can be thought of as the class of relations on ω that would be computable by a super-mind capable of completing an effectively specified ω-sequence of tasks, in which case Δ^1_1 is to Δ^0_1 as $\prod^1_1$ is to $\sum^0_1$; this analogy was one of the starting points for generalized recursion theory. The class of ramified-analytical sets (= RA_α for $\alpha = \beta_0$) is a proper subset of Δ^1_2.

5 Hierarchies of relations between reals

So far we have only considered relations on ω defined by formulae of L_1; but a formula of L_1 whose only free-variables are one-place predicate-variables defines a relation between reals, that is, on Power(ω) = the class of reals. Such a relation is analytical iff it is defined in this way, allowing bound predicate-variables to range over Power(ω); it is arithmetical iff it is defined by such a formula with no bound predicate-variables (which formula may be classified like one of L_0). Thus we have an arithmetical and analytical hierarchy of such relations; for $i \in \{0,1\}, R \subseteq \mathrm{Power}(\omega)^{\mathrm{m}}\colon \mathrm{R} \in \sum^{\mathrm{i}}_{\mathrm{n}}$ iff *R* is so defined by a $\sum^i_n$ formula of L_1; $R \in \prod^i_n$ iff *R* is so defined by a $\prod^i_n$ formula.

Similarly, if we use 'ramified' definitions we obtain the *HA* hierarchy, and, going further, the *RA* hierarchy, of relations between reals. In the 1950s J. Addison (in his 1954 doctoral dissertation and in Addison (1959)) pointed out that the *HA* and analytical hierarchies of such relations where the 'effective analogues' of the so-called Borel and projective hierarchies, studied by French and Russian analysts (for example, E. Borel, H. Lesbesque, M. Suslin and N. Lusin) in the early twentieth century. Their work, usually labelled 'descriptive set-theory', was thought of as a part of topology; apparently the logicians (except for Mostowski) had worked in complete ignorance of it. Contemporary descriptive set-theory emerged from this cross-pollination as a hybrid of recursion theory and topology.

6 Other hierarchies

There is at least one interesting hierarchy within the class of recursive relations, the so-called Grzegorczyk hierarchy. Even further 'low-down' (within the class of primitive-recursive relations) hierarchies have been proposed by computer-scientists, though here as this writing (1993) ignorance outstrips knowledge (see Complexity, computational). The study of such animals is usually called 'subrecursion theory'.

All hierarchies discussed here classify relation on ω or on Power (ω). Practitioners of generalized recursion theory have generalized some of these hierarchies to classify relations on other classes of mathematical objects.

Reduction, problems of

Reduction is a procedure whereby a given domain of items (for example, objects, properties, concepts, laws, facts, theories, languages, and so on) is shown to be either absorbable into, or dispensable in favour of, another domain. When this happens, the one domain is said to be 'reduced' to the other. For example, it has been claimed that numbers can be reduced to sets (and hence number theory to set theory), that chemical properties like solubility in water or valence have been reduced to properties of molecules and atoms, and that laws of optics are reducible to principles of electromagnetic theory. When one speaks of 'reductionism', one has in mind a specific claim to the effect that a particular domain (for example, the mental) is reducible to another (for example, the biological, the computational). The expression is sometimes used to refer to a global thesis to the effect that all the special sciences, for example chemistry, biology, psychology, are reducible ultimately to fundamental physics. Such a view is also known as the doctrine of the 'unity of science'.

1 Reduction by derivation and definition

Unity and simplicity are often touted as important virtues achieved through reduction (see Unity of science). By reducing one domain to another, we show the reduced domain to be either part of the second or eliminable in favour of it. Depending on the nature of the entities reduced, reduction will, therefore, promote ontological or conceptual economy and unity. When numbers have been reduced to sets, numbers no longer need be countenanced over and above sets; numerical concepts can be explained in terms of notions involving only sets; and laws about numbers follow from principles about sets. There will often be an explanatory gain as well: when gas laws are reduced to principles of statistical mechanics, via the kinetic theory of gases, we have an explanation of why these gas laws hold to the extent that they do - why the pressure, temperature and volume of gases behave (roughly) in accordance with the gas laws. Furthermore, reduction is sometimes thought of as a way of vindicating or grounding a possibly suspect domain of entities; if number theory is successfully reduced to logic, as Frege claimed, that would show number theory to be as firm and well-grounded as laws of logic. If the mental realm is reducible to the physical-biological domain, this would remove whatever problems and doubts might becloud the scientific status of the mental. Such are the thoughts and aspirations that inspire and sustain reductive projects and reductionisms.

There are apparently simple cases of reduction in which logical-mathematical derivation alone suffices for reduction. When Galileo's law of free fall or Kepler's laws of planetary motion are derived from the principles of Newtonian mechanics in conjunction with applicable force laws (see Mechanics, classical §2), they are reductively absorbed into a more general and comprehensive theoretical framework.

According to logical behaviourism, mental expressions are definable - that is, given synonymous translations - in terms of expressions referring to actual or possible behaviour ('behaviour dispositions'). Logical behaviourism, therefore, exemplifies an attempt to reduce the mental to the physical-behavioural through definition (see Behaviourism, analytic). Thus, one way to reduce a domain of expressions, or concepts, is to provide each expression with a definition couched solely in the expressions of the base domain. On the assumption that synonymous expressions refer to the same entities, a definitional reduction would also accomplish an ontological reduction: entities referred to by the first group of expressions have been shown to be among those referred to by the second group.

Reduction becomes more complex for domains that do not yield to direct derivational or definitional relationships, as in the case of reductions involving theories each with its own distinctive vocabulary, for example the reduction of thermodynamics to statistical mechanics.

2 The Nagel model of reduction

Ernest Nagel (1961) articulated a model of reduction for scientific theories that has served as the principal reference point in discussions of reduction (see Theories, scientific). The guiding idea of this model remains derivation, but Nagel saw that to derive laws of a theory from another which does not share the same vocabulary, certain 'bridge principles' must be assumed as additional premises. Consider two theories, T_1 and T_2, each with its distinctive vocabulary, V_1 and V_2, where T_2 is the candidate for reduction and T_1 the reduction base.

Theories in this context are construed as sets of laws. Nagel's model requires that there be connecting laws, standardly called 'bridge laws', correlating terms of V_2 with terms of V_1. What form do such laws take and how many are needed for reduction? The simple answer is that they must be available in sufficient numbers and be sufficiently powerful to enable the derivation of T_2-laws from T_1-laws. But that depends on the strengths of the specific theories involved. The only general requirement worth considering, therefore, is the following:

The condition of connectibility: For each primitive *n*-place predicate *F* of V_2, there is a predicate *G* of V_1, such that for any $x_1, \ldots, x_n$ (in the domain of entities covered by the two theories), it is a law that $F(x_1, \ldots, x_n)$ if and only if $G(x_1, \ldots, x_n)$.

Thus, each predicate of the theory to be reduced must be connected, via a *biconditional law*, with a nomologically coextensive predicate of the reducer. These bridge laws in effect licence the rewriting of every T_2-law as a T_1-statement; in general, they enable the translation of T_2-statements into the language of T_1. Thus, the only difference between Nagel reduction and definitional reduction is that in the former the translation is underwritten by empirical laws whereas in the latter it is based on meaning equivalences.

There is a sense in which the condition of connectibility alone guarantees reduction: if any T_1-rewrite of a T_2-law is not derivable from the laws of T_1 as they stand, simply add it to T_1 as a new law (assuming it, as well as the original T_1-laws, to be true). This would extend the base theory, but not its vocabulary; and the extension would be warranted since the base theory was incomplete in failing to capture a true law statable in its vocabulary: namely, the T_1-rewrite of the T_2-law.

It is evident that when a theory has been derivationally reduced, it is conserved as part of the base theory; its laws are shown to be 'derivative laws' of a more comprehensive theory. Moreover, the condition of connectibility ensures that the properties posited by the reduced theory find their nomic equivalents in the reduction base, with which they may ultimately be identified when a successful reduction becomes entrenched. Thus, Nagel reduction is a species of 'conservative' (or 'retentive') reduction, which conserves, and can legitimize, that which is reduced; it contrasts with 'eliminative' reduction which dispenses with what has been reduced.

3 Emendations to the Nagel model: the Kemeny-Oppenheim model

Nagel's model has been criticized on various grounds, of which the following three are perhaps the most important. First, biconditional bridge laws are too weak, and must be strengthened into identities if they are to yield genuine reductions (Sklar 1967; Causey 1977). We need, it is argued, the identity 'temperature = mean molecular kinetic energy', not just a law that merely affirms covariance of the two magnitudes. As long as the reduction falls short of identifying them, there would be temperatures as properties of physical systems 'over and above' their microstructural properties. Moreover such correlations ('nomological danglers') cry out for an explanation: why does temperature covary in just this way with mean molecular kinetic energy? By identifying them we provide a short and conclusive answer: because they are in fact one and the same.

Second, the reduced theory is often only approximately true, and its laws are derivable only under special simplifying assumptions (which, strictly speaking, are false). For example, in deriving the gas laws in kinetic theory of gases, one has to make various assumptions, such as that collisions between molecules are perfectly elastic, that molecules are point masses, and so on. And the laws hold only approximately and within a fairly narrow range of conditions. Third, it is often pointed out that the condition of connectibility, which requires biconditional bridge laws, is unrealistic and can seldom be satisfied. Thus, temperature cannot, it is claimed, be uniformly correlated, or identified, with a single micro-based property; it may be mean kinetic energy of molecules for gases, but something else for solids or in vacuums.

As a response to the second criticism, it has been suggested (Schaffner 1967; Churchland 1986) that the reduction of T_2 to T_1 should require only that a *corrected version* of T_2 (or its 'image' in T_1), rather than T_2 itself, be derivable from T_1. We may also explicitly allow special limiting assumptions of the sort mentioned earlier. But to what extent can we correct or revise a theory without turning it into another theory? Obviously, the required corrections must be such as to yield the necessary bridge laws or identities, but there is no guarantee that any reasonable amount of tinkering will suffice to accomplish this. This takes us back to the last of the objections mentioned above.

Kemeny and Oppenheim (1956) proposed a model of reduction that departs extensively from the Nagel model, giving us a broader conception of reduction that does not require connecting principles between the theories involved. The gist of the new model can be stated thus: T_2 is *Kemeny-Oppenheim reduced* to T_1 just in case all observational data explainable by T_2 are explainable by T_1. This definition can, and should, be understood in a way that does not presuppose a context-independent theory-observation distinction or any special conception of explanation. The core idea here is that anything, be it an observation or a low-level empirical generalization or law, that the reduced theory can explain, or predict, should be explainable and predictable by the base theory. The base theory, then, is at least as powerful, as an explanatory and predictive instrument, as the theory being reduced, making the latter at best otiose. This means that the reduced theory is ripe for elimination - unless, that is, it is also Nagel-reducible, and hence conserved as a subtheory of the reducer. Notice that any case of Nagel reduction is also a case of Kemeny-Oppenheim reduction (at least, on the standard deductive-nomological account of explanation; see Explanation §2). Unlike the Nagel model, the Kemeny-Oppenheim model requires no direct relationship between the reduced theory and its reducer; in particular, it involves no bridge laws of any form. In fact, the reduced theory may be false and the reducer true. However, it assumes that the two theories concern the same domain of phenomena (at least, that the domain of the reduced theory is included in that of the reducer). In any case, the Kemeny-Oppenheim model allows the replacement, or elimination, of the reduced theory, and hence can serve as a model of 'eliminative' reduction.

4 Microreduction and microdeterminism

A pervasive trend in modern science has been to explain macrophenomena in terms of their microstructures, and reduce theories about the former to theories about the latter. Examples abound in the physical and biological sciences. The reduction of thermodynamics to statistical mechanics (see Thermodynamics), the reduction of optics to electromagnetic theory (see Optics §1), the successes in solid-state physics and molecular biology (see Genetics; Molecular biology; Sociobiology), and a host of other examples appear to attest to the fruitfulness of microreduction as a research strategy (Oppenheim and Putnam 1958).

Both the Nagel and the Kemeny-Oppenheim models can be applied to microreduction. What is needed is the idea that one theory is a *microtheory* in relation to another. The rough idea is that the microtheory deals with objects that are*proper parts* of the objects in the domain of the macro-theory. More specifically, the domain of the microtheory will include objects that are parts of the objects in the domain of the macrotheory; in addition it will include aggregates of these micro-objects, and aggregates of aggregates, and so on. And the objects of the macrotheory are identified with certain complex aggregates in this domain. Moreover, the microtheory has a set of properties and relations characterizing its basic micro-objects, and will generate complex properties for aggregates of these objects from the basic properties and relations. These micro-based properties (for example, mean molecular kinetic energy of a gas) of aggregative structures of micro-objects are important for reduction: in Nagel reductions, it is these micro-based properties that will be correlated (or identified) by bridge laws with the properties of the macrotheory; in Kemeny-Oppenheim reductions, they will be needed in providing explanations of the data explained by the macrotheory.

The metaphysical underpinning of microreduction is the principle of *microdeterminism* or *mereological supervenience*: properties of a whole are wholly determined by, or supervenient on, the properties and relations characterizing its proper parts. No matter how complex an object (say, a human being, a planetary system) may be, if you put together qualitatively indistinguishable parts in the same structural relationship, you will get an exact duplicate of that object (barring basic physical indeterminacies). It is the task of science, then, to identify a physically significant decomposition of a whole into parts and develop a microtheory about these parts that will explain why the whole has the properties it has.

5 Multiple (or variable) realization and reduction

One influential objection often deployed against the claim that a given theory is reducible to another is 'the multiple realization argument'. This argument was initially developed as an objection against mind-body reduction, but has been used to argue for the impossibility of reduction almost everywhere (Fodor 1974). Consider a higher level property, such as pain: pain as a psychological state is 'realized' by diverse physical-biological processes in widely divergent organisms and structures. The neural realizer of pain in humans probably has little in common with its realizer in octopuses; nor can we a priori exclude the nomological possibility of pain in inorganic

electro-mechanical systems. This means that there is no single physical-biological state which could be correlated, or identified, with pain in a biconditional bridge law, and this defeats Nagel reduction of any theory of pain to an underlying physical-biological theory, as well as reductive identification of pain with a physical-biological state. The same argument is often applied to biological concepts, such as ‘heart’ and ‘digestive system’, functionally defined physical concepts like ‘carburettor’ and ‘thermometer’, and dispositional concepts like ‘transparency’ and ‘water solubility’.

Notice that the multiple realization argument does not touch Kemeny-Oppenheim reduction in general, but works only against Nagel reduction which, as we saw, aims to conserve the reduced higher level properties. In any case, one reply that is usually rejected is this: why not reduce pain to a *disjunction* of its diverse physical realizers? But given the kind of extreme diversity involved, such disjunctive states are unlikely to be projectible nomic properties and there cannot, it seems, be a unitary theory dealing with them (Kim 1992). Another, more plausible, way of dealing with the phenomenon of multiple realization is to lower our reductive aspirations: the argument perhaps shows that *uniform* or *global reduction* of pain is not feasible, but not that human pain, octopus pain and Martian pain cannot each be *locally reduced* to human physiology, octopus physiology and Martian electrochemistry, respectively (Kim 1992). Thus, multiple realization is consistent with (in fact, it arguably entails) the local reducibility of higher level sciences: for example, human psychology to human neurobiology, octopus psychology to octopus neurobiology, and so on. One possible difficulty with this approach is that pain, when considered multiply reduced to a set of diverse physical-biological bases, seems to lose its integrity as a single mental state; pain as such appears either eliminated or else remains unreduced outside the ontology of the lower level theories.

6 The primacy of physical theory

Physics is generally thought to be our basic science, the only science that aspires to ‘full coverage’ of all of the natural world. But what does this mean? Does it mean that all the special sciences - that is, laws and generalizations of these sciences and the properties posited by them - are reducible to the basic laws of physics and fundamental physical properties? It used to be thought that the primacy of physical theory was equivalent to global physical reductionism. This view will be rejected by most philosophers. Many now doubt the possibility of reduction in almost all areas of science, and downplay the scientific and philosophical significance of reductions (although of course no one has seriously suggested that we would ever actually achieve a single unified science in the vocabulary of basic microphysics). Some have argued that even where reductions are possible, we lose important explanatory information about phenomena in a given domain when we focus only on their microstructures and neglect the larger ‘patterns’ that emerge at macrolevels. These macropatterns are claimed to cut across microstructures, and be capturable only by higher level laws (Fodor 1974). These remain controversial issues, however.

Views of this kind resemble the position of emergentism (Morgan 1923) on higher level ‘emergent’ properties. Those who hold these or related views often try to explain the primacy of physical theory in a thesis of supervenience or determination, the claim that physical facts (including physical laws) determine all the facts, or that worlds that are indiscernible in respect of all physical features are one and the same world (Hellman and Thompson 1975; Kim 1984). However, the relationship between reductionism and various forms of the supervenience thesis remains controversial and continues to be debated (Kim 1984).

Reductionism in the philosophy of mind

Reductionism in the philosophy of mind is one of the options available to those who think that humans and the human mind are part of the natural physical world. Reductionists seek to integrate the mind and mental phenomena - fear, pain, anger and the like - with the natural world by showing them to be natural phenomena. Their inspirations are the famous reductions of science: of the heat of gases to molecular motion, of lightning to electric discharge, of the gene to the DNA molecule and the like. Reductionists hope to show a similar relationship between mental kinds and neurophysiological kinds.

1 The road to functionalism

Reductionism in the philosophy of mind is generated by an apparent conflict between two conceptions of persons. The first we inherit from our general culture, and is often called folk psychology. Folk psychology portrays humans as having experiences, emotions, purposes, thoughts about and expectations of the world: humans are conscious intentional agents (see Folk psychology). According to the picture we derive from the natural sciences, humans are evolved animals, and animals are nothing more than complex physical systems. Reductionist strategies in the philosophy of mind all start from a firm commitment to this second conception: the idea that humans are part of the natural order. That natural order is not essentially mysterious or occult. So reductionists accept some version of physicalism (see Materialism in the philosophy of mind).

Reductionist programmes in the philosophy of mind face three problems. (1) Are humans part of the natural order - is the physicalist conception true? (2) If we are part of the natural order, does folk psychology fit, or fail to fit, with that conception? (3) What do we need to do in order to integrate folk psychology within the naturalistic conception?

It has often been thought that no physicalist theory of consciousness or subjective experience is possible; these phenomena show the outright falsity of physicalism. For example, there seems to be a fundamental contrast between my knowledge of my own mind and my knowledge of the physical world. The latter is error-prone: it is conceivable that we could be wrong in any belief about the physical world. But it is not even conceivable, the idea runs, that I am wrong in thinking that I feel sleepy. I could be wrong about the causes of the feeling, but not that I have that feeling (see Introspection; Qualia).

There are three options available for those who think humans are part of an unmysterious natural order. One idea (the ‘No real problem’ option) is that the dualists’ puzzles of how thought and consciousness fit into the natural order evaporate on a proper understanding of the nature of folk psychology. Properly understood, the folk conception of the mental is unproblematic. The strategy seeks to show that mental concepts are equivalent to, or translate into, concepts for quite innocent phenomena. The most famous variant of this line is behaviourism. Behaviourists think that mental kinds have behavioural signatures; the essence of anger, for instance, is not a particular kind of internal mental event, but a way of behaving. A claim that a person is conscious, or intelligent, or is purposive is not about their inner workings or organization. It is not a claim about the causal structure that produces behaviour; but rather about the pattern of that behaviour. It is a claim that therefore cannot, of its very nature, traffic in weird causes or weird stuff (see Behaviourism, analytic).

The eliminativist option takes the conflict between folk psychology and the idea that humans are part of the natural order to be irresolvable. They think we cannot accept the view that we are conscious intentional agents and the view that we are part of the natural order. They furthermore suggest that the folk conception must be rejected, forced as we are to choose between them. So the eliminativist proposes to abandon the folk conception of the mind (see Eliminativism).

That leaves the reductionists. They accept (1) that folk conceptions of the mental do make claims about the causal structures that produce behaviour, and (2) that folk psychologists’ inventory of mental events, processes and kinds must be shown to be compatible with the view that the mind is a wholly natural phenomenon. If folk psychology offers an incomplete but more or less correct account of some of the causal structure underlying human behaviour, and if humans are just complex physical systems, then the events, processes and properties named in folk psychology must be physical events, processes and properties.

Identity theorists developed for philosophy of mind ideas then current in the philosophy of science about the relationship between less and more fundamental sciences (see Mind, identity theory of). The idea was that a less fundamental domain could be reduced to a more fundamental domain via bridge laws that linked the domains. Thus the chemical property of valency might be linked to atomic physics via bridge laws that identified different elements' valencies with properties of their electron structure. In the philosophy of mind, this became the identity theory, holding that

Mental states = states of the central nervous system.

In J.J.C. Smart's most famous example (1959), perhaps pain just is C-fibre stimulation. If identity hypotheses can be defended for all mental states, events and processes, then facts about the mental would be reduced to facts about neural structures, events and processes.

When the identity theory was formulated in the 1950s, it had to fight against the idea that it was conceptually confused. How could physicalism be true without being obviously true? The defenders of the theory had to show that one could master and understand the language of folk psychology without any mastery of the language of the neurosciences. They had to show how it is possible to know that you are in pain without knowing, say, that your C-fibres are being stimulated.

Identity theorists met these challenges through example and analysis. Though lightning is nothing but the discharge of static electricity we can understand lightning and know plenty about lightning without knowing its physical nature. Until the discovery of the structure of DNA, population geneticists talked of genes without knowing their chemical nature. Genes were identified by their role in inheritance and development. We can understand concepts for kinds, and know something about these kinds without knowing about their intrinsic characteristics. Smart re-reinforced these examples with a 'topic neutral analysis' of mental concepts. To say that you are experiencing blue visual sensations, for example, is just to say that the experiences you are now having are similar to those you have when you see a blue wall in good light. It is obviously possible both to learn and correctly deploy topic neutral sensation concepts without knowing anything about the intrinsic nature of those sensations.

The identity theory however proved to be chauvinist in Ned Block's terminology (1978). If pain is C-fibre stimulation, then if you have no C-fibres, you cannot feel pain. Yet it is surely possible, and perhaps even actual, for organisms with different neurophysiologies to feel pain. It seemed to be a mistake to tie our account of what cognition is too closely to the details of how our brain works. So the identity theory does not quite show how it is possible to be both a folk psychologist and a reductionist.

2 Functionalism

So most current reductionists accept some version of functionalism. The many forms of that doctrine are united in holding that the essential feature of any mental state is its causal role (see Functionalism). For example, all instances of fear have a distinctive causal role: fear has a characteristic profile of causes and effects. But functionalists also claim that fear is realized by a physiological state: most probably a complex of hormonal activity and arousal of the nervous system. The functional role of fear is occupied by a physiological state. If functionalists are right, our mental life can be described in complementary ways. A functional description tells us the causal roles of the full range of human psychological states. A physical description specifies the physical states which have those causal roles. The attraction of functionalism as a theory of mind is its attempt to reconcile physicalism with folk psychology.

The relationship between functional kinds and their physical realizations is complex. Two different people can be in the same mental state, hold the same belief, for instance. A functional description specifying a certain causal role is true of them both. Psychological kinds can be multiply realized. The neural organization of our memory is flexible and shows a good deal of individual variation, so the same mental state can have different physical realizations in different people, or in the same person at different times. These complications are magnified when we consider psychological states - fear, for example - that we share with other animals. Furthermore, if there are intelligent aliens or robots, then there are systems whose intelligence has a very different physical basis from ours. So the one mental state might have wildly varied physical realizations.

The functionalist pictures psychological kinds as realized by neural kinds in complex and varied ways. So the natural kinds of psychology are not identical to the natural kinds of the physical basis of the mind. Hence, despite the fact that we are nothing but complex physical systems, functionalists often claim that psychology is relatively independent of the sciences of the brain. The functionalist programme needs to show (1) that a reductionist strategy of some kind is needed, that against the no real problem option it really is necessary to demonstrate the connection between the folk psychological and the natural science picture; (2) that folk psychology can be properly built into the physicalist world view through the idea of functional kinds as merely realized by physical kinds, and (3) that it really is plausible that all psychological kinds are some species of functional kind.

3 ‘No problem’ theories

Behaviourism is no longer widely accepted, but it is still argued that there is no potential for conflict between folk psychology and the natural sciences because folk psychology is an instrument: its use is instrumental or practical rather than theoretical. The contrast here is with the so-called ‘theory-theory’: folk psychology as an implicit theory of the causes of human behaviour. Like other theories, such a theory would need to be integrated with the rest of the natural sciences; like other theories, it could be wrong and shown to be wrong by its conflict with, or isolation from, the rest of our picture of nature.

The theory-theory may well over-intellectualize folk psychology. Folk psychology is not part of a conscious research programme into the structure of the human mind. Our use of it may be as much knowing how as knowing that. Nevertheless, folk psychology is full of claims about human minds, and about the causes of human behaviour: about, for instance, beliefs and desires causing behaviour (‘They went because they believed that they would enjoy themselves’), and about perceptions causing beliefs (‘Seeing is believing’). Paul Churchland (1981) has given one set of arguments for the theory-theory: folk psychology can be assembled into a package of generalizations connecting perceptions, thought and behaviour. Folk psychology can be organized in such a way that there are structural similarities between it and paradigm scientific theories. But a potential for conflict between the natural sciences and folk psychology does not depend on accepting a full-blooded version of the theory-theory. An analogy with other folk crafts should make that clear. The folk agriculture of, say, a New Zealand Maori tribe is not research science. It includes as much knowledge how as knowledge that. Its uses are practical. Yet none of that made it invulnerable to advances in scientific knowledge. Its central categories might turn out to be empty, to be misconceived, if their failure to correspond to the causes of growth are radical enough. Potential for conflict depends only on the idea that practices, modes of practical knowledge and skill, can depend on or presuppose conceptions of the causal structure of a domain. Even if folk psychology has different goals or purposes from the scientific behavioural sciences the demand that folk psychology be shown to be compatible with a naturalistic conception of human nature is still reasonable. An analogy with folk medicine is compelling. What would we think of a claim for the therapeutic value of some practice where we could find no physiological mechanism that would explain that value? Or, still worse, where our physiological sciences seem to show that the practice could not have therapeutic value?

4 What does physicalism require?

Though the matter remains very controversial, in my view the ‘no real problem’ option is not attractive. Folk psychology seems to make claims about the working of the human mind, about its causal structure, whose relation to the natural sciences requires explanation. But it has proved very difficult to formulate precisely this idea of demonstrating compatibility between two conceptions of human nature. At the very least, folk psychological states must supervene on the physical world. There can be no change in my folk psychological state - say, from fear to calm - without some change in my intrinsic or relational physical properties (see Supervenience of the mental). But the eliminativists argue for a much stronger condition, something close to the original idea of the identity theory’s bridge laws between the domains of psychology and neurophysiology. They argue that without a strong condition, spurious compatibility is too easy to construct, and the debris of intellectual history will escape appropriate rejection.

Despite the eliminativists’ claims, the idea that folk psychology requires bridge laws for its vindication is clearly much too strong. The double descriptions characteristic of the functionalist idea is not a fancy trick dreamed up just for the philosophy of mind. The distinction between a role and its occupant is not restricted to psychology. We can make the same distinction in politics between, say, the chief justice and the particular person who occupies

that role. We can ask questions about that role; about the legal and constitutional powers of the chief justice. We can ask questions about the occupier: about their political background and skills; about size, sex or place of birth. We can make the same distinction in biology. Zoologists investigate the causal role echo-location plays in the life of the bat. They measure the discriminatory capacities and range of the system, test its role in hunting, courtship and mating. Neuroethologists investigate the physical systems that occupy that causal role in the bat.

The idea of multiple realization is not restricted to the relationship between mental state types and the neural states realizing those types. There are no simple bridge laws between classical genetics and molecular genetics, the science which is rightly seen as vindicating classical genetics. The bodily effects of DNA sequences depend very much on the cellular environment of those DNA sequences plus many other factors. So the geneticists' fruit-fly gene for red eyes is not identical to a particular DNA sequence: there is no DNA sequence that always and only produces red-eyed fruit-flies (see Genetics). So the complexity of the relationship between functional state and physical realization is not a feature just of the relationship between folk psychology and neuroscience; it is common to many of these other domains as well.

Nonetheless if folk psychological kinds are parts of causal explanations within human psychology, an explanation of their capacity to play that causal role does seem needed. Causal powers stand in need of explanation. There is a tree of explanatory dependence that links together causal mechanisms. That tree is rooted in fundamental physical kinds and processes. Through various different branchings, all scientific kinds depend on that taproot. The kinds (and the processes in which they take part) further out in the branches need to be explained by kinds and laws closer to the root.

The importance of this idea is seen in its regulative role in scientific debate. For example, the biogeographic and geological evidence for continental drift was quite impressive even before the Second World War. But continental drift remained marginalized in the profession, in part because the proposed mechanisms to shift continents were impossible. The drifters of the 1930s conceived of continents as ploughing through somewhat less dense ocean floor rather as a concrete slab might be pushed half through, half over the top, of a layer of earth. The proposed forces were too weak, and the stresses on continental crusts would be far too great for them to survive the passage. Until drift could be plausibly placed in the explanatory tree, driftist explanations of movement were hard to accept.

There have been similar problems with mechanism in recent debates within evolutionary theory. From time to time there are announcements of counterexamples to Crick's central dogma of molecular biology, nucleic acids code proteins, but not vice versa; changes in the protein envelope of the nuclear material do not result in reverse transcription, changing RNA and thence DNA (though reverse transcription form RNA to DNA is possible). There is no plausible mechanism through which three dimensional form can be transcribed into two dimensional form, hence no mechanism through which acquired characteristics can be inherited through changes in DNA. A discoverer of the inheritance of acquired characteristics would need to give some account of a mechanism of inheritance.

The reductionist debate has not been concluded. A precise and plausible formulation of the physicalist constraint remains elusive. Many psychological kinds continue to resist functionalist theory: if they have a characteristic causal role, that causal role has been difficult to characterize. The appropriate formulation of functionalism remains a matter of intense debate.

Reference

It is usual to think that referential relations hold between language and thoughts on one hand, and the world on the other. The most striking example of such a relation is the naming relation, which holds between the name 'Socrates' and the famous philosopher Socrates. Indeed, some philosophers in effect restrict the vague word 'reference' to the naming relation, or something similar. Others use 'reference' broadly (as it is used in this entry) to cover a range of semantically significant relations that hold between various sorts of terms and the world: between 'philosopher' and all philosophers, for example. Other words used for one or other of these relations include 'designation', 'denotation', 'signification', 'application' and 'satisfaction'.

Philosophers often are interested in reference because they take it to be the core of meaning. Thus, the fact that 'Socrates' refers to that famous philosopher is the core of the name's meaning and hence of its contribution to the meaning of any sentence - for example, 'Socrates is wise' - that contains the name. The name's referent contributes to the sentence's meaning by contributing to its truth-condition: 'Socrates is wise' is true if and only if the object referred to by 'Socrates' is wise.

The first question that arises about the reference of a term is: what does the term refer to? Sometimes the answer seems obvious - for example, 'Socrates' refers to the famous philosopher - although even the obvious answer has been denied on occasions. On other occasions, the answer is not obvious. Does 'wise' refer to the property wisdom, the set of wise things, or each and every wise thing? Clearly, answers to this should be influenced by one's ontology, or general view of what exists. Thus, a nominalist who thinks that properties do not really exist, and that talk of them is a mere manner of speaking, would not take 'wise' to refer to the property wisdom.

The central question about reference is: in virtue of what does a term have its reference? Answering this requires a theory that explains the term's relation to its referent. There has been a great surge of interest in theories of reference in this century.

What used to be the most popular theory about the reference of proper names arose from the views of Gottlob Frege and Bertrand Russell and became known as 'the description theory'. According to this theory, the meaning of a name is given by a definite description - an expression of the form 'the F' - that competent speakers associate with the name; thus, the meaning of 'Aristotle' might be given by 'the last great philosopher of antiquity'. So the answer to our central question would be that a name refers to a certain object because that object is picked out by the name's associated description.

Around 1970, several criticisms were made of the description theory by Saul Kripke and Keith Donnellan; in particular, they argued that a competent speaker usually does not have sufficient knowledge of the referent to associate a reference-determining description. Under their influence, many adopted 'the historical-causal theory' of names. According to this theory, a name refers to its bearer in virtue of standing in an appropriate causal relation to the bearer.

Description theories are popular also for words other than names. Similar responses were made to many of these theories in the 1970s. Thus, Kripke and Hilary Putnam rejected description theories of natural-kind terms like 'gold' and proposed historical-causal replacements.

Many other words (for example, adjectives, adverbs and verbs) seem to be referential. However we need not assume that all other words are. It seems preferable to see some words as syncategorematic, contributing structural elements rather than referents to the truth-conditions and meanings of sentences. Perhaps this is the right way to view words like 'not' and the quantifiers (like 'all', 'most' and 'few').

The referential roles of anaphoric (cross-referential) terms are intricate. These terms depend for their reference on other expressions in their verbal context. Sometimes they are what Peter Geach calls 'pronouns of laziness', going proxy for other expressions in the context; at other times they function like bound variables in logic. Geach's argument that every anaphoric term can be treated in one of these two ways was challenged by Gareth Evans.

Finally, there has been an interest in 'naturalizing' reference, explaining it in scientifically acceptable terms.

Attempted explanations have appealed to one or more of three causal relations between words and the world: historical, reliable and teleological.

1 Millian and description theories of proper names

The description theory of proper names stands in sharp contrast to the age-old and attractive theory that there is no more to a name's meaning than its role of designating something. Thus, John Stuart Mill claimed that 'proper names are not connotative: they denote the individuals who are called by them; but they do not indicate or imply any attributes as belonging to those individuals' ([1843] 1867: 20) (see Mill, J.S. §2). One problem for this theory is that it makes answering our central question seem hard: if a name does not 'imply any attributes' of its bearer, as the description theory claims it does, what determines which object is the bearer?

It was not primarily concern with this question, however, that led most philosophers to abandon the Millian theory and adopt the description theory. They did this largely as a result of the criticisms and counter-proposals of Frege (1893) and Russell (1911).

The most famous criticism of the Millian theory concerns identity statements. The ancient Greeks observed what they took to be a star rising in the evening and called it 'Hesperus', and what they took to be another star rising in the morning and called it 'Phosphorus'. In fact these 'two stars' were the planet Venus. Consider the following two statements:

(1) Hesperus is Phosphorus.
(2) Hesperus is Hesperus.

Sentence (1) is true. A comparison of (1) and (2) seems to indicate that they differ sharply in meaning. Various reasons have been adduced in favour of this view. Some philosophers have argued that whereas (1) is synthetic, (2) is analytic; others that whereas (1) is known empirically, (2) is known a priori; still others that whereas (1) is contingent, (2) is necessary. However, probably the most influential reason for thinking that the statements differ in meaning has been Frege's claim that they differ in 'cognitive value': (1) is highly informative, revealing an important astronomical discovery, whereas (2) is uninformative, a trivial piece of logical knowledge (see Frege, G. §3). In any case, it was generally agreed that the two statements do differ in meaning. If so, the only way to explain this seemed to be to attribute different meanings to 'Hesperus' and 'Phosphorus'. Yet, according to the Millian theory, they must have the same meaning as they both have the role of designating Venus. So the Millian theory must be wrong: a name's role of designating its bearer does not exhaust its meaning.

Another important criticism concerns existence statements. 'Vulcan does not exist' is true. Because it is true, 'Vulcan' does not designate anything. So, according to the Millian theory, 'Vulcan' should be meaningless. So, 'Vulcan does not exist' should be partly meaningless. Yet, it is perfectly meaningful. Indeed, if it were not, it could not be true. So, once again, the Millian theory must be wrong (see Fiction, semantics of).

The description theory provides neat solutions to what are problems for the Millian theory. According to the description theory, a name in effect abbreviates the definite description that competent speakers associate with the name: thus 'Aristotle' might abbreviate 'the last great philosopher of antiquity'. So it is easy to see why (1) and (2) differ in meaning: 'Hesperus' might be associated with the description 'the star that rises in the evening', and 'Phosphorus' with 'the star that rises in the morning'. And 'Vulcan does not exist' is fully meaningful because 'Vulcan' abbreviates the meaningful description 'the planet in orbit between Mercury and the Sun' (see Proper names §§1, 5).

More importantly for our purposes, the description theory provides an answer to our central question. A name designates a certain object because that object is denoted by the definite description associated with the name; 'Aristotle' designates Aristotle because 'the last great philosopher of antiquity' denotes him. Of course, this answer raises another question (see §6): in virtue of what does the description denote that object? Still, progress has clearly been made because we had that problem anyway.

Some obvious problems with this 'classical' description theory - including the problem that speakers differ in the descriptions that they associate with a name - led some philosophers, notably John Searle (1958) and Peter Strawson (1959), to modify the theory. A name is not tied tightly to one description but loosely to many. It can

designate its bearer despite the failure of some in its 'cluster' of associated descriptions to denote that object: it designates whatever object most of the descriptions in the cluster denote.

2 Three arguments against description theories of proper names

Description theories dominated for half a century until challenged by three arguments around 1970: the unwanted necessity and rigidity arguments, both due largely to Kripke (1980), and the argument from ignorance and error, due to Kripke and to Donnellan (1972).

Unwanted necessities were one of the obvious problems for the classical description theory. If 'the last great philosopher of antiquity' is synonymous with 'Aristotle', then 'Aristotle is a philosopher' should be necessarily true (provided Aristotle exists). Yet it is not: Aristotle might have died young, long before his philosophical fulfilment. The cluster theory avoided this version of the problem. The description 'the last great philosopher of antiquity' is just one among many in the cluster that expresses the meaning of 'Aristotle'. Aristotle need not have any particular one of the many properties specified by the cluster. The cluster theory does require, however, that Aristotle have *most* of the properties specified by the cluster. Kripke points out how implausible this is. Aristotle might not have had any of the properties commonly associated with him: he might not have been a pupil of Plato, taught Alexander the Great, and so on. So 'Aristotle' cannot be synonymous with the cluster of associated descriptions (see Kripke, S.A. §2).

The rigidity argument deploys the notion of 'rigid designation'. This is explained as follows: for a term *a* to be a rigid designator is for it to designate the same object in every possible world (in which it designates at all), or, less picturesquely, for it to be such that '*a* is *F*' would truly characterize some non-actual situation if and only if the object that the term *actually* designates were *F* in that situation. Kripke argues that names are rigid designators whereas the descriptions alleged to be synonymous with them are not. So description theories are wrong. Consider:

(3) Aristotle was fond of dogs.
(4) The last great philosopher of antiquity was fond of dogs.

Suppose that Aristotle had indeed died young. Then Plato, not Aristotle, would have been the last great philosopher of antiquity. In those circumstances the truth of (4) would depend on whether Plato was fond of dogs. But the truth of (3) would still depend, just as it does depend in the actual world, on whether Aristotle was fond of dogs. The name 'Aristotle' designates Aristotle in a non-actual situation just as it does in the actual situation, whereas the description 'the last great philosopher of antiquity' designates whoever is the last great philosopher of antiquity in that situation, whether Aristotle or not. So the name is not synonymous with the description. Similarly, it is not synonymous with any other description, or cluster of descriptions, that is a candidate to give its meaning. (Note that in assessing rigidity we are evaluating the truth and reference of our expressions with the meanings that they actually have as a result of our usage, but we consider them as used to characterize hypothetical situations. Of course, any expression could have a different meaning as a result of different usage in a non-actual situation - language is 'arbitrary' - but that is beside the point) (see Proper names §§2-3).

Statements (3) and (4) are not modal statements (although we have been evaluating them as characterizations of non-actual situations). Other versions of the rigidity argument concern modal statements. For example, whereas 'Hesperus is necessarily Hesperus' is true, 'Hesperus is necessarily the star that rises in the evening' is not: had the solar system been differently arranged, Hesperus might not have been visible in the evening but it still would have been Hesperus. This sort of difference between descriptions and names in modal statements had been emphasized earlier by other philosophers, particularly Ruth Barcan Marcus (1961).

Some philosophers, notably Michael Dummett (1973), resisted Kripke's two arguments by focusing on modal statements. These philosophers exploited the well-known ambiguities of scope in these statements to undermine the apparent difference between names and descriptions. Whatever the truth of this matter, the apparent difference in nonmodal statements remains.

These two arguments challenge the description theory as a theory of the meaning of a name, a meaning that determines the name's reference. This is how the theory is naturally understood. However, as Kripke points out, the theory could be understood as simply a theory of reference: the reference of a name is fixed by a description, but the name is not synonymous with that description. This weaker theory is impervious to the two arguments. Of

course, the weak theory has a defect: because it is no longer a theory of meaning, it no longer solves the problems that troubled the Millian theory. Indeed, the relation between meaning and reference becomes a pressing issue on the basis of this theory.

There is another way of saving the description theory from the two arguments while avoiding this defect. Instead of weakening the original theory into a mere theory of reference, we revise it along the following lines: a name is synonymous with a ‘rigidified’ description. Our language already seems to have descriptions that contain ‘rigidity operators’; for example, the italicized part of ‘the person who, *in the actual world*, is the last great philosopher of antiquity’ seems to make this description designate Aristotle in every possible world. If descriptions of this sort are indeed rigid, the revised theory claims that a name is synonymous with such a description. If such descriptions are not rigid, the revised theory can claim that the name itself supplies the rigidity operator and so would be synonymous with an ordinary nonrigid description governed by that operator.

All of these description theories - original, weak and revised - have the consequence that the users of a name associate with it a description that identifies its bearer. The third argument against description theories, the argument from ignorance and error, challenges this. So, if the argument is good, it counts against all description theories.

The argument shows that people who seem perfectly able to designate with a name are very often too ignorant to supply an identifying description. Thus some may fail with the name ‘Cicero’ because they associate with it only the description ‘a famous Roman orator’, which applies to many people. Others may fail because they associate ‘the man who denounced Catiline’ with ‘Cicero’ and are unable to supply an appropriate description for ‘Catiline’: the description that they associate with ‘Catiline’ is ‘the man denounced by Cicero’, which takes us in a circle and leaves both names without reference, according to the description theory.

The argument shows also that people often associate with a name a description that identifies something other than the name’s bearer: they are simply wrong about the bearer. Thus some associate ‘the inventor of the atomic bomb’ with ‘Einstein’ and some associate ‘the first person to realize that the world was round’ with ‘Columbus’. Almost everyone who has heard of Peano associates ‘the discoverer of Peano’s axioms’ with ‘Peano’, but the axioms were actually discovered by Dedekind. Despite such errors, people succeed in designating Einstein, Columbus and Peano by their names.

The description theory can be improved by allowing people to ‘borrow’ their reference from others. So the description Martha associates with ‘Einstein’ might be ‘the person Joe referred to yesterday as "Einstein"’. Provided Joe can supply an appropriate description - either one that describes Einstein directly or one that borrows reference from someone who can supply an appropriate description - Martha will succeed in designating Einstein. There is a danger of a circle, of course. Apart from that, there are problems of ignorance and error once more. Perhaps Martha cannot remember the reference lender; or she can remember the lender by his name, ‘Joe’, but cannot supply the identifying description that the theory requires; or the lender is identified but he cannot identify Einstein, perhaps identifying something else instead. The description theory still seems to place too great an epistemic burden on speakers.

An argument from ignorance and error can also be brought against another, more general, theory that some - for example, Dummett - have taken from Frege. This is the theory that to understand a name a person must be able to ‘identify’ its bearer. This ability is usually evidenced by providing a description, but it may be evidenced by ‘recognizing’ the bearer. The epistemic burden that this more general theory places on speakers still seems too great.

Various moves have been made to save the description theory in the face of these difficulties. Most popular, perhaps, have been theories that the reference of, for example, ‘Einstein’ is determined by a description along the lines of ‘the person referred to by (called, named and so on) "Einstein"’, for this description does identify Einstein and speakers surely associate it with the name. However, such theories still risk circularity.

3 General terms and mass terms

Just as there are description theories of names, so also there are description theories of general terms like ‘tiger’, ‘hammer’ and ‘bachelor’, and of mass terms like ‘gold’ and ‘paper’ (see Mass terms). Speakers of the language

associate various descriptions with a term. One of these descriptions, or most of a cluster of them, expresses the meaning of the term and determines what it applies to. If only one description does the job, the view is analogous to the classical description theory of names. If a cluster of descriptions does, the view is analogous to the cluster theory of names.

Kripke (1980) and Putnam (1975) argued that description theories are false of general and mass terms that apply to natural kinds. So they are false of ‘tiger’ and ‘gold’. The arguments are like the three against description theories of names (see §2). First, the theories yield unwanted necessities. The description we associate with ‘tiger’ is along the lines of ‘large carnivorous quadrupedal feline, tawny yellow in colour with blackish transverse stripes and white belly’. Yet it is not necessary that a tiger has four legs and is striped: a tiger might lose a leg, or in a different environment tigers might not be striped. Second, the term ‘gold’ is a rigid designator, applying to the same kind of stuff in every possible world. In contrast, an associated description like ‘dense yellow metal’ is nonrigid. Third, people who seem perfectly able to use a term are often too ignorant or misguided about the things to which it applies to supply an appropriate identifying description. Thus, some who use ‘elm’ and ‘beech’ cannot supply descriptions that distinguish elms from beeches; many who use ‘gold’ cannot distinguish gold from fool’s gold; it was once common to associate ‘fish’ with ‘whale’.

Putnam added a further argument built around the following fantasy. Imagine that somewhere in the galaxy there is a planet, Twin Earth. Twin Earth, as its name suggests, is very like Earth. In particular, each Earthling has a *doppelgänger* on Twin Earth who is a cell for cell duplicate of the Earthling. Twin Earth differs from Earth in one respect, however: the stuff that the Twin Earthians who appear to speak English call ‘water’, stuff that is superficially indistinguishable from what we call ‘water’, is not H_2O but a very different compound XYZ. So Oscar on Earth and Twin Oscar on Twin Earth are referring to different stuff by ‘water’. Yet Oscar and Twin Oscar are *doppelgängers*, associating exactly the same descriptions with ‘water’ (which is more plausible if we place Oscar and Twin Oscar in 1750 before the chemical composition of water was known). So those associations are not sufficient to determine reference and the description theory is wrong. Indeed, nothing happening in the head is sufficient to determine reference. As Putnam put it, ‘meanings just ain’t in the head’ (see Content: wide and narrow; Putnam, H. §3).

We have considered criticisms of description theories of proper names and natural-kind words. Do these criticisms extend to description theories of other words? Putnam took the arguments to apply to almost all words, including ‘pencil’ and ‘paediatrician’. Tyler Burge (1979) took a similar line, arguing that the meanings (contents) and references of a wide range of a person’s words and accompanying thoughts are not ‘individualistic’ in that they are not determined simply by that person’s intrinsic states. To a large extent they are determined by the person’s social context. Burge’s examples include ‘arthritis’, ‘sofa’, ‘brisket’, ‘clavichord’ and ‘contract’ (see Methodological individualism).

The Twin Earth fantasy brings out an important feature of description theories in general: even if a description theory gives the right answer to our central question for some word, its answer is incomplete. Thus, consider a description theory of ‘tiger’. According to the theory, the reference of ‘tiger’ is determined by the reference of such words as ‘carnivorous’ and ‘striped’. Suppose, contrary to the arguments above, that this were so. We then need to explain the reference of those words to complete the explanation of the reference of ‘tiger’. Description theories might be offered again. But then the explanation will still be incomplete. At some point we must offer a theory of reference that does not make the reference of one word parasitic on that of other words. We need an ‘ultimate’ explanation of reference that relates some words directly to the world, if there is to be any reference at all.

4 Historical-causal theories

Kripke and Donnellan followed their criticism of description theories of names with an alternative view. This became known as the ‘causal’ or ‘historical’ theory, although Kripke and Donnellan regarded their view as more of a ‘picture’ than a theory (see Proper names §4).

The basic idea of this theory is that a name designates whatever is causally linked to it in an appropriate way, a way that does not require speakers to associate an identifying description of the bearer with the name. Reference is initially fixed at a dubbing, either by perception or description of the referent. The name is then passed on from

person to person in communicative exchanges. People succeed in designating an object with a name because underlying their uses of the name are causal chains stretching back to the dubbing of the object with the name. People borrow their reference from people earlier in the chain but borrowers do not have to remember lenders; it is enough that borrowers are, as a matter of historical fact, appropriately linked to their lenders in communication. So people can designate Cicero despite their ignorance of him, or designate Einstein despite their errors about him.

Similarly, Kripke and Putnam proposed an historical-causal theory of natural-kind words. Reference is initially fixed at a dubbing, either by description or perception of samples of the kind. The reference is then to all those objects, or all that stuff, having an internal structure of the same sort as the samples: for example, in the case of gold having the atomic number 79. People at a dubbing lend their reference to others, who can then lend it to still others. People who are ignorant about the kind can use the word to refer to the kind's members because underlying the use of the word are causal chains stretching back to a dubbing.

In thus removing the epistemic burden on speakers, historical-causal theories are a radical departure from the Frege-Russell tradition. That tradition assumes that those who understand a name must know about its meaning and reference, so that if its reference is determined in a certain way, they must know that it is. The historical-causal theory must reject the assumption that speakers have this privileged 'Cartesian' access to semantic facts: the reference of a name is determined by causal chains that are likely to be beyond the ken of the ordinary speaker. Once again, we must conclude with Putnam that 'meanings just ain't in the head'. This very feature of the theory has led many to reject it and to work hard to preserve the description theory (or the more general 'identification theory' favoured by Dummett; see §3). From the traditional Cartesian perspective, the causal theory's failure to impose an epistemic burden rules it out as a candidate to explain reference.

The historical-causal theory nicely captures the rigidity of names: the reference of a name is determined by its *actual* causal relations, something that cannot change when we consider other possible worlds. Less pleasingly, by rejecting any descriptive element to the meaning of a name, the theory may seem to leave no alternative but to resurrect the Millian view, identifying a name's meaning with its role of designating its bearer. Many philosophers, influenced by the 'direct reference' approach to indexicals (see §5), have taken this route, despite the problems for the Millian view (see §1). To avoid this it seems that we must explain a name's meaning in terms of the particular sort of causal chain that determines the name's reference.

The theory faces problems arising from various confusions and mistakes that can play a role in forming the causal network underlying a name. And it must explain how the reference of a name can change even though the historical fact of the dubbing cannot change. In developing the theory to deal with these problems, Michael Devitt (1981) has emphasized that a name is typically 'grounded' in its bearer in many perceptual confrontations after the initial dubbing: it is 'multiply' grounded in its bearer.

The historical-causal theory is returned to in §8.

5 Indexicals

To answer our central question for indexicals - terms like 'I', 'now', 'here', 'you', 'she', 'that' and 'this table' - we need to consider how the context of their utterance determines their reference.

Both Russell (1918) and Hans Reichenbach (1947) explain the reference of all indexicals (called 'egocentric particulars' by Russell and 'token-reflexive words' by Reichenbach) in terms of the reference of 'this'. Thus, Reichenbach claims that '"I" means the same as "the person who utters this token"; "now" means the same as "the time at which this token is uttered"; "this table" means the same as "the table pointed to by a gesture accompanying this token"' (1947: 284). This amounts to a description theory of reference for all indexicals except 'this token' in terms of the reference of 'this token'.

Any description theory of an indexical may face arguments of the usual three sorts: unwanted necessities, rigidity, and ignorance and error. The theory is particularly vulnerable to the argument from rigidity, as David Kaplan (1989) showed. (Kaplan prefers to talk of the closely related notion of 'direct reference' rather than 'rigidity'.) Thus, compare:

(5) This table is green

and Reichenbach's interpretation of it:

(6) The table pointed to by a gesture accompanying this token is green.

Suppose that the table referred to is in fact green, so that (5) and (6) both assert true propositions. Consider now a situation in which that table was still green but the furniture had been moved around so that a different table, a brown one, would be the subject of the gesture. Would those propositions asserted by (5) and (6) still be true? (Note that this question concerns the propositions actually asserted by (5) and (6), not the propositions that would have been asserted by the sentences in that non-actual situation.) Kaplan argues that whereas what (6) asserts would be false, what (5) asserts would still be true. The indexical 'this table' is rigid, referring to the same table in each possible world, whereas the description 'the table pointed to by a gesture accompanying this token' is nonrigid, referring to whatever table fits that description in the possible world. So the demonstrative is not synonymous with the description.

Apart from this, a general theoretical consideration counts against a description theory of indexicals. We have noted the essential incompleteness of description theories (see §3): even if a description theory is right for some word, the theory's explanation must rest ultimately on the reference of some other words which must be explained nondescriptively. Indexicals seem to be the most plausible candidates for nondescriptive explanation, more so even than proper names or natural-kind words: indexicals seem to be the place where language stands in its most direct relationship to the world.

In seeking a nondescriptive theory, it helps to follow Kaplan in dividing indexicals into two groups: 'pure indexicals' like 'I', 'here' and 'now', and 'demonstratives' like 'she', 'that' and 'this table'. The nondescriptive explanations of pure indexicals are fairly simple: 'I' designates the speaker of the utterance, 'here' the place of the utterance, 'now' the time of the utterance, and so on. (These explanations may seem to be description theories once again, but they are crucially different. For example, the last explanation is not that 'now' designates the time of the utterance because it is synonymous with an associated description 'the time of this utterance', but rather, because it is governed by the rule that it designates that time.) Demonstratives are more difficult to explain.

There are three basic ideas for a nondescriptive explanation of demonstratives. According to the first, a demonstrative designates the object demonstrated by the speaker. One problem with this idea is that a demonstration is often so vague that it alone would not distinguish one object from many others in the environment. A more serious problem is that demonstratives are not always accompanied by a demonstration. Thus, where only one table is prominent in the environment, the speaker may use 'this table' without a demonstration. And reference is often to an object that is not around to be demonstrated: for example, 'That drunk at the party last night was offensive'.

According to the second idea for a nondescriptive explanation, a demonstrative designates the object that the speaker intends to refer to. Even if this is so, it does not take us far because it raises the question: in virtue of what does the speaker intend to refer to that object? This is very similar to the original problem.

According to the third idea - urged, for example, by Edmund Husserl (1900-1) - a demonstrative designates the object in which it is based perceptually (compare the perceptually based grounding of a name according to the historical-causal theory). So 'this table' designates a certain table in virtue of the fact that it was perception of that table that led to the utterance; similarly 'that drunk at the party' designates the person that caused the remark (see Demonstratives and indexicals).

6 Descriptions

Definite descriptions have the form, 'the *F*', and indefinite descriptions the form, 'a/an *F*'. In his theory of descriptions, Russell (1905) claimed that 'the *F* is *G*' is equivalent to 'there is something that is alone in being an *F* and it is *G*'; and 'an *F* is *G*' is equivalent to 'there is something that is an *F* and it is *G*'. So the descriptions are to be understood in terms of the general term, '*F*' and the existential quantifier, 'there is something'.

Under the influence particularly of Donnellan (1966), many now think that a description is 'ambiguous', having not only this 'attributive' meaning captured by Russell but also a 'referential' meaning like that of a name or demonstrative.

It has been generally agreed that descriptions have a referential use as well as an attributive use. Used attributively, ‘the *F*’ conveys a thought about whatever is alone in being *F*; ‘an *F*’ conveys a thought about some *F* or other. Used referentially, each description conveys a thought about a particular *F* that the speaker has in mind, a thought about a certain *F*. Thus, consider:

(7) The murderer of Smith is insane

used in the following two contexts. (a) We come upon Smith foully murdered. We have no idea who is responsible but the brutal manner of the killing leads us to utter (7). Its description is used attributively. (b) We observe Jones on trial for Smith’s murder. The oddity of his behaviour leads us to utter (7). Its description is used referentially. Next, consider:

(8) A man in a red cap stole Anne’s computer

used in the following two contexts. (c) Anne’s computer is discovered missing in the morning. We find signs that the burglar made a hasty escape dropping a red cap in the alley. This leads us to utter (8). Its description is used attributively. (d) After discovering that Anne’s computer is missing we remember noticing a man in a red cap behaving suspiciously earlier in the day. We utter (8) to report our suspicions to the boss. Its description is used referentially.

Despite agreement that there are these two uses, there is no agreement that descriptions are ambiguous. Appealing to ideas prominent in the work of H.P. Grice (1989), many have defended Russell. They argue that a speaker can use a description referentially, thus making the object in mind the ‘speaker referent’, even though that object is not the semantic referent. Whether a speaker has an object in mind or not, the truth-conditions of the sentence are as specified by Russell. The referential use is pragmatically, but not semantically, different from the attributive use (see Pragmatics §§3-4, 8). Thus, in context (b), although Jones is the speaker referent, the truth of (7) will depend on the sanity of whoever murdered Smith, whether Jones or not. And in context (d), although the man behaving suspiciously is the speaker referent, the truth of (8) will depend on whether some man or other in a red cap stole the computer.

Against this, many have found reasons for thinking that in contexts like (b) and (d) the speaker referent is also the semantic referent and hence that descriptions are semantically ambiguous after all. Some of these reasons - for example, those arising from failures to describe correctly the object in mind and from the behaviour of descriptions in opaque contexts - have not stood up well. Others seem more promising. First, we are not just able to use descriptions referentially, it seems that we regularly do so. This regularity suggests that there is a convention of so using descriptions. If there is, then it is hard to see why the convention is not semantic. Second, in their referential uses descriptions seem to have roles just like demonstratives: ‘the *F*’ and ‘an *F*’ function like ‘that *F*’, and are similarly based on perception of a particular object. To try to treat these demonstratives like Russellian descriptions would be to give a description theory of them, and we have already noted problems for this (see §5). Third, definite (but not indefinite) descriptions seem to have the same range of anaphoric roles as a pronoun like ‘she’ (see §7). We might then expect them also to share the pronoun’s role as a demonstrative which, as has already been pointed out, seems not to be Russellian. Fourth, consider the utterance, ‘The book is on the table’. In the right circumstances, this will seem true and yet, according to the Russellian view, it must be false: since the world is full of books and tables the two definite descriptions fail to describe unique objects. The obvious modification to save the Russellian view is to treat these ‘incomplete’ descriptions as elliptical. But this modification has problems. A speaker may have many ways to complete the description and there may be no basis for saying that any one is the correct way. Alternatively, trying to complete the description may lead to the familiar problems of ignorance and error.

Another argument against the ambiguity thesis appeals to rigidity. If referential uses of descriptions were semantically significant then, it is claimed, they should be rigid like names and demonstratives. Yet they do not seem to be. Consider the use of ‘Smith’s murderer’ in context (b) above. ‘Smith’s murderer is insane’ does not seem to be true in a world where Smith is alive and well, even if Jones is insane. However, this argument has a problem: the referential use of the demonstrative ‘that murderer’ would equally seem to fail this rigidity test in these circumstances (hence suggesting a need to revise Kaplan’s claims about demonstratives; see §5). Yet a demonstrative surely has a semantically significant referential use. If so, then a description may have one too,

despite not being rigid (see Descriptions).

7 Other terms

Many terms that we have not discussed - like adjectives, adverbs and verbs - are naturally taken to refer. It is certainly no easier to explain reference for these terms than for the terms discussed, but we may hope that doing so will not pose sharply different problems (see Adverbs; Predication).

We must also consider sentential operators like ‘and’ and ‘not’, and quantifiers like ‘every pen’, ‘some stones’, ‘most dogs’ and ‘few bachelors’. Perhaps these should be seen as largely syncategorematic (see Logical constants; Quantifiers). If we are prepared to accept the existence of certain abstract entities, however, we can take these expressions as referential also. Thus we can take ‘and’ as denoting a ‘truth function’ *conjunction* which is such that the sentence ‘*p* and *q*’ is true if and only if ‘*p*’ is true and ‘*q*’ is true. The quantifiers involve a ‘determiner’ and a general term, and can be taken as applying to sets. Thus ‘most dogs’ involves the determiner ‘most’ and the general term ‘dogs’ and can be taken as applying to any set that contains more than half the dogs; and the sentence ‘most dogs bark’ is true if and only if there is such a set and ‘bark’ applies to all its members.

In virtue of what do these expressions have these referents? The most promising answer for the sentential operators has two stages. We start by describing the ‘conceptual role’ of the operator in deductive, inductive and practical inferences. For a token to denote ‘conjunction’ it must have the appropriate conceptual role. But in virtue of what should we assign to a token with that role the denotation ‘conjunction’ rather than, say, ‘disjunction’? Because, under that assignment, deductive inferences are truth-preserving, inductive inferences are reliable, and so on. A similar line is presumably part of the answer for the quantifiers: ‘most dogs’ applies to any set containing most dogs (rather than, say, to any set containing a few cats) partly because of the reference of ‘dogs’ and partly because of the conceptual role of the determiner ‘most’ and the reliability of inferences. A worrying feature of both these answers is that they seem to make widespread irrationality impossible (see Semantics, conceptual role).

Finally, we must consider anaphoric terms. Pronouns, and even definite descriptions, often depend for their reference on other expressions in their verbal context. Thus ‘one’ in ‘John owns a car and Alice owns one too’ is (using Geach’s term) a ‘pronoun of laziness’, going proxy for the noun phrase ‘a car’ in the preceding conjunct. And consider ‘he’ in ‘John is happiest when he is alone’ and in ‘Every man knows a woman that he admires’. In the former sentence ‘he’ is naturally seen as coreferential with ‘John’, in the latter as ‘bound by’ the quantifier ‘every man’ and so functioning like a bound variable in logic.

Geach (1962) has argued that all anaphoric pronouns are either pronouns of laziness or bound by quantifier antecedents. Against this Evans (1985) has argued that some pronouns with quantifier antecedents are unbound. He calls these ‘E-type’. (a) Consider:

(9) Few congressmen admire the president, and they are very junior.

If ‘they’ were bound by ‘few congressmen’, (9) should mean that few congressmen both admire the president and are very junior. But it does not. The first clause of (9) entails that few congressmen admire the president; the second that all of those who do admire him are very junior. (b) If ‘they’ were bound in (9), then we should be able to substitute any quantifier for ‘few congressmen’ and still make sense. But ‘No congressmen admire the president, and they are very junior’ does not make sense. (c) Last, consider:

(10) If many men come to the ball, Mary will dance with them.

The quantifier ‘many men’ could bind ‘them’ only if (10) meant ‘Many men are such that if they come to the ball Mary will dance with them’, which is not the natural reading. As a result of these considerations and others - particularly pronouns in one person’s sentence that are anaphoric on quantifiers in another person’s - it is generally agreed that Evans has identified a distinct type of pronoun.

However, Evans’ view of this type has been challenged. He thinks that the reference of such a pronoun is determined in a Russellian way by a definite description that can be derived from its quantified antecedent; thus, the reference of ‘they’ in (9) is determined by ‘the few congressmen who admire the president’, and that of ‘them’ in (10) by ‘the many men who come to the ball’. Because these are definite descriptions, for (9) to be true *all* the Kennedy admirers must be junior, and for (10) to be true Mary must dance with *all* the men who come. This

consequence does not seem to generalize. ‘Some congressmen admire the president, and they are very junior’ seems to be compatible with some other congressmen admiring him and not being very junior. The problem is more acute in singular cases: ‘Socrates owned a dog and it bit him’ seems to be compatible with Socrates owning another dog which did not bite him. Finally, there are the formidably difficult ‘donkey sentences’: ‘Every man that owns a donkey beats it’ and ‘If John owns a donkey, he beats it’. On one reading, these sentences concern not simply the unique donkey of each donkey owner but *all* the owner’s donkeys (see Anaphora).

8 Naturalizing reference

From a naturalistic perspective, reference must ultimately be explained in scientifically acceptable terms. Attempted explanations have appealed to one or more of three causal relations between words and the world: historical, reliable and teleological.

Historical-causal theory of reference. Kripke, Donnellan and Putnam (see §4) did not claim to be naturalizing reference, but their theories - together with the role that perception of an object may play in determining the reference of demonstratives and referential descriptions (see §§5-6) - suggest the idea that reference might be explained naturalistically in historical-causal terms: a token refers to the object that played the appropriate role in causing it. But this idea, developed by Devitt, faces the *qua*-problem. In virtue of what is ‘Aristotle’, say, perceptually grounded in a ‘whole object’ and not a time-slice or undetached part of the object, each of which is equally present and causally efficacious? The problem is more pressing for natural-kind words. ‘Horse’ is grounded in a few horses. But those objects are not only horses, they are mammals, vertebrates and so on; they are members of very many natural kinds. Indeed, any horse is a member of indefinitely many *non*-natural kinds: it may be a pet, an investment and so on. In virtue of what is ‘horse’ grounded in an object *qua* horse, rather than *qua* mammal, pet, or whatever? So in virtue of what does it refer, as a result of such groundings, to all and only horses rather than all and only mammals, pets, or whatever?

Reliabilist theory of reference. Under the influence particularly of Fred Dretske (1981) and Jerry Fodor (1990), ‘reliabilist’, ‘informational’, or ‘indicator’ theories have been popular. The basic idea is that a token refers to objects of a certain sort because tokens of that type are reliably correlated with the presence of those objects; the tokens are ‘caused by’ those objects. The token ‘carries the information’ that a certain situation holds in much the same way that tree rings carry information about the age of a tree. There is a problem. How can the theory allow for error? Occasionally we see a muddy zebra and wrongly think ‘horse’. So, some zebras are among the things that would cause tokens of ‘horse’. What ‘horse’ is reliably correlated with is really the presence of horses, muddy zebras, the odd cow in bad light and so forth. So according to reliabilism, it should refer to horses, muddy zebras, the odd cow and so on (with the result that it was not wrong to think ‘horse’ after all). The problem is that many things that a token of a certain type does not refer to, including some denizens of Twin Earth, would cause a token of that type (see Semantics, informational).

Teleological theory of reference. Most fully developed by Ruth Millikan (1984), teleological theories explain the reference of a token in terms of its function, where that function is explained causally along Darwinian lines: a token’s function is what tokens of that type do that explains why they exist. This theory deals neatly with the problem of error because something - for example, sperm - can have a function which it does not reliably perform. An immediate consequence of the theory is that a token of a type that has not evolved will lack a referent. So the ‘thoughts’ and ‘utterances’ of an exact replica of Russell created by some cosmic accident would have no reference. This strikes many as implausible but is accepted by the theory’s proponents. To complete the theory it must be shown that tokens - even a belief like ‘computers make writing easier’ which could not plausibly be taken as innate - have a function in the required biological sense and that this function does indeed relate the token to its referent. Millikan has attempted this formidable task (see Semantics, teleological).

9 Further issues

Terms in opaque or intensional contexts cannot be seen as having their usual referential roles. For, in these contexts, particularly those of propositional attitude ascriptions (see Propositional attitude statements), the replacement of a term by a coreferential term may not preserve truth.

There are a range of what might be called ‘negative’ views of reference. (a) Some philosophers have a

‘deflationary’ view according to which there is nothing more to referential notions than is captured by all instances of a schema like ‘*e* designates *a*’, where what is substituted for ‘*a*’ ‘translates’ what is named by the term substituted for ‘*e*’; ‘"Socrates" designates Socrates’ is a typical instance. This view accompanies a similarly deflationary view of truth (see Truth, deflationary theories of). (b) W.V. Quine (1960) argues that even once the translation of a sentence has been fixed the reference of any part of the sentence is inscrutable; thus there is no fact of the matter whether an alien’s ‘Gavagai’ in response to an environment of rabbits refers to rabbits, undetached rabbit parts, time-slices of rabbits, and so on (see Radical translation and radical interpretation §§1-4). Related to this, Donald Davidson (1984) takes an instrumentalist attitude to reference, denying both the need for, and the possibility of, a theory of reference. Putnam (1983) gives a model-theoretic argument that reference is indeterminate because any theory has unintended models. (c) Kripke (1982) presents an argument (which he finds in Ludwig Wittgenstein’s discussion of rule-following) that the meanings and references of terms are not determinate (see Meaning and rule-following). (d) Less sweepingly, Hartry Field (1973) has argued that in some cases there is no determinate matter of fact whether a term refers to one thing or another and we should see it as ‘partially referring’ to both: for example, ‘mass’ as used by Newtonians does not determinately refer to either proper mass or relativistic mass but partially refers to both. (e) Finally, those in the ‘structuralist’ tradition reject reference, and hence its role in meaning, altogether. They apparently think that the only possible theory of reference is one according to which a word resembles what it refers to. But this theory is refuted by the fact that language is arbitrary, by the fact that anything could be used to mean anything. Reference is thus left as simply ‘God-given’, which is unacceptable (see Structuralism in linguistics).

Finally, views on reference can bear on realist notions about the external world (see Realism and antirealism). Putnam, for example, draws antirealist conclusions from his model-theoretic argument. And consider the consequences of a holistic description theory for scientific terms. When, in time, we come to replace one scientific theory with another, it is natural to think that part of the reason we do so is that the theory does not accurately describe reality. Combine this thought with the holistic view that the reference of each term in the theory is determined by its associations with all other terms in the theory, and we get the consequence that all terms in the theory fail to refer. So, it was a mistake to believe in the entities apparently referred to by that theory. Worse, it is probably a mistake to believe in the entities of our present theory, for that theory will surely be replaced in time too. So we should not be scientific realists. Indeed, these considerations lead Thomas S. Kuhn (1970) and others to constructivism, a radically relativistic antirealism: rather than saying that the replaced theory does not describe reality, they say that it describes *its* reality, a reality that only exists relative to that theory (see Constructivism). Each theory has its own reality and no sense can be made of scientific entities existing ‘absolutely’. This line of thought can be resisted by rejecting the holistic description theory of reference in favour of a localist theory, perhaps one explaining reference in terms of causal relations to reality (see Holism: mental and semantic).

Reichenbach, Hans (1891-1953)

Philosophy of science flourished in the twentieth century, partly as a result of extraordinary progress in the sciences themselves, but mainly because of the efforts of philosophers who were scientifically knowledgeable and who remained abreast of new scientific achievements. Hans Reichenbach was a pioneer in this philosophical development; he studied physics and mathematics in several of the great German scientific centres and later spent a number of years as a colleague of Einstein in Berlin. Early in his career he followed Kant, but later reacted against his philosophy, arguing that it was inconsistent with twentieth-century physics.

Reichenbach was not only a philosopher of science, but also a scientific philosopher. He insisted that philosophy should adhere to the same standards of precision and rigour as the natural sciences. He unconditionally rejected speculative metaphysics and theology because their claims could not be substantiated either a priori, on the basis of logic and mathematics, or a posteriori, on the basis of sense-experience. In this respect he agreed with the logical positivists of the Vienna Circle, but because of other profound disagreements he was never actually a positivist. He was, instead, the leading member of the group of logical empiricists centred in Berlin.

Although his writings span many subjects Reichenbach is best known for his work in two main areas: induction and probability, and the philosophy of space and time. In the former he developed a theory of probability and induction that contained his answer to Hume's problem of the justification of induction. Because of his view that all our knowledge of the world is probabilistic, this work had fundamental epistemological significance. In philosophy of physics he offered epoch-making contributions to the foundations of the theory of relativity, undermining space and time as Kantian synthetic a priori categories.

1 Life

Hans Reichenbach was born in Hamburg, Germany, on 26 September 1891, where he grew up and received his primary and secondary education. In 1910 he went to Stuttgart to study engineering, but found the subject intellectually unsatisfying. He soon shifted to mathematics, physics and philosophy, which he pursued at the Universities of Berlin, Göttingen and Munich under such teachers as Max Born, Ernst Cassirer, David Hilbert and Max Planck. During the First World War he served in the German Signal Corps at the Russian front, but returned to his academic work after suffering a severe illness.

Reichenbach wrote his doctoral dissertation (1916) on the applicability of mathematical probability to the physical world; he received his degree at Erlangen in 1915. In the following year he passed a state examination in physics and mathematics at Göttingen. From then until 1920 he held a regular job in the radio industry, while pursuing academic work on a part-time basis. During that time Einstein offered his first seminar in the theory of relativity in Berlin; Reichenbach attended and established a lasting relationship with him. In 1920 he returned to Stuttgart to teach at the Technische Hochschule. In 1926, due mainly to Einstein's influence, he became Professor of Philosophy of Physics in Berlin, where he remained until Hitler's rise to power in 1933. At that time he fled to Turkey, where he taught philosophy at the University of Istanbul. In 1938 he moved to the University of California at Los Angeles, where he remained until his death from a heart attack on 9 April 1953.

2 Epistemology

Early in the twentieth century, many scientifically minded philosophers, impressed by new developments in logic and other epistemological considerations, maintained that the entire world could be viewed as a logical construction from sensations (see Phenomenalism §1; Neutral monism). This view appealed strongly to some of the logical positivists, especially Rudolf Carnap, who attempted to carry out the construction in detail (1928); it represented the epitome of logical positivism (see Carnap, R. §1). In his review of this book, Reichenbach (1933) praised its precision and scope, but expressed one misgiving. He could see no place for probability in the positivistic approach (see Logical positivism §2).

Reichenbach (1938) developed the issue of probability into a full-scale attack on logical positivism. He elaborated three major points. First, whereas the positivists had insisted that a statement must be fully verifiable in principle to be cognitively meaningful, Reichenbach enunciated a principle that required only probabilistic support (see Demarcation problem §3). Second, he denied that our factual knowledge must be based on incorrigible reports of

sensory experience; he maintained that it is founded on fallible perceptions of middle-sized physical objects and is probabilistic from the ground up. Third, he maintained that we can have probabilistic knowledge of unobservable physical entities. The atom is not a construct out of sense impressions; it is a physical object whose reality we can infer probabilistically (seeScientific realism and antirealism §4). Atoms would exist even if there were no sentient beings in the universe. This was his refutation of logical positivism.

3 Induction and probability

The concept of probability was one of Reichenbach's major concerns throughout his career; his main treatise on the subject is *The Theory of Probability* (1949). He argued that probability should be understood as the limit of a sequence of relative frequencies. Suppose, for example, that we have a coin that can be flipped in the standard way. We begin flipping the coin, and keeping track of the result (heads or tails) of each toss: H T T H T H H H T H…. This generates a sequence of fractions m/n representing the number of times *m* that heads has shown in *n* tosses of the coin: $\frac{1}{1}, \frac{1}{2}, \frac{1}{3}, \frac{2}{4}, \frac{2}{5}, \frac{3}{6}, \frac{4}{7}, \frac{5}{8}, \frac{5}{9}, \frac{6}{10}$, …. If this sequence of fractions has a limit, that is, if the members of this sequence become and remain arbitrarily close to some value (say $\frac{1}{2}$) as the sequence is extended indefinitely, then that limit *constitutes* the probability of heads on flips of that coin.

This concept of probability leads to many problems. First, we have no guarantee that such a limit exists; these fractions can continue fluctuating forever without approaching any particular value. Aware of this problem, Reichenbach noted its relationship to Hume's problem of justifying induction. Hume argued correctly that we have no guarantee that nature is uniform - that the future will be like the past. Similarly, since we have no guarantee that our particular sequence of coin tosses will exhibit the statistical regularity of converging to a limit, we have no guarantee that the probability in question exists. Nevertheless, we are justified in *positing* that the observed frequency in an initial section of the sequence approximates the limiting frequency, even though that posit may be incorrect. The justification is pragmatic. First, if no limit exists, we will be wrong in our posits, but no other method would succeed, for there is no limit to be discovered. Second, there may be a limit, but it may be quite different from the frequency in the observed initial portion of the sequence. It follows from the definition of 'limit', however, that persistent use of this method, 'the rule of induction', will eventually lead to posits that are accurate to any desired degree of approximation. In ascertaining probabilities (that is, limiting frequencies) we have everything to gain and nothing to lose by using the inductive method (see Induction, epistemic issues in §2; Inductive inference §§1-2; Probability theory and epistemology §1).

Why should we want to ascertain probabilities? According to Reichenbach, all of our knowledge, scientific or common-sensical, is probabilistic; moreover the frequency interpretation is the only legitimate interpretation of probability. Thus, the ascertainment of probabilities (limiting frequencies) is fundamental to all our knowledge. Unfortunately, as Reichenbach acknowledged, his justification applies to an infinite class of other rules - asymptotic rules - that direct us to posit $m/n + c_n$ where c_n is a 'corrective term' that approaches zero as *n* approaches infinity. He had no satisfactory way of showing that his rule is superior to any other asymptotic rule. The best we can say, perhaps, is that the addition of an arbitrary c_n to the observed frequency would be epistemologically unsupportable.

Reichenbach's claim that the frequency interpretation is the only legitimate one poses two other major problems. First, in many practical situations we must deal with single events rather than long sequences - for example, buying an insurance policy. Reichenbach argued that such cases can be handled by assigning the single case to an appropriate sequence and transferring the probability in the sequence, as a weight, to the single case. This will be a successful strategy if one deals with large numbers of diverse single cases. The second major problem - a special case of the first - is the probabilities of hypotheses. A given hypothesis is either true or false, just as a given toss of a coin comes up heads or tails. How can probabilities of hypotheses be construed in terms of relative frequencies? Reichenbach stated that Bayes' theorem in the probability calculus enables us to handle this problem, but he never clearly explained how.

4 Space and time

Reichenbach wrote four major treatises on space and time (1920, 1924, 1928, 1956); in the first he attempted a compromise between Kant and Einstein, but in the later works he severed his ties with Kant completely. In his

classic work, *Philosophie der Raum-Zeit-Lehre (The Philosophy of Space and Time)* (1928), he argued that the question of the geometrical structure of physical space is a matter to be decided, not a priori, but by empirical science. The situation is, however, rather complicated. The discovery of non-Euclidean geometries early in the nineteenth century did not refute Kant, even after the proof of relative consistency (if the non-Euclidean geometries are self-contradictory then so is Euclidean geometry). Kant had claimed that Euclidean geometry is synthetic; if its denial were logically inconsistent, then it would be analytic. Kant's view had been that Euclidean geometry is epistemologically, not logically, privileged; it is a necessary form of visualization of the physical world. Reichenbach argued in detail that the non-Euclidean geometries are possible forms of visualization. (Recall that Einstein had chosen non-Euclidean geometry to formulate his General Theory of Relativity before 1920.) The question is which geometry provides the most suitable one (see Space; Spacetime).

Certain facts about two-dimensional geometry were well-known in the nineteenth century. For example, in Euclidean geometry the sum of the angles of a triangle is exactly $180°$; in non-Euclidean geometries this sum is either greater or less than $180°$, and the value of the sum differs for triangles of different areas. It might seem that we could ascertain the geometry of physical space by measuring angular sums of triangles with various orientations in three-dimensional space. However, at the turn of the century Henri Poincaré had realized that to determine geometrical features of physical space we must use physical measuring instruments, and the results will depend upon the behaviour of these instruments (Poincaré 1902). According to Reichenbach, Poincaré held that the geometry of space is a matter of pure convention; although we could use any geometry we wished to describe physical space, we actually choose Euclidean geometry because it is simpler than non-Euclidean geometries.

Although Reichenbach has often been called a 'conventionalist', he was actually an anti-conventionalist regarding physical geometry (see Conventionalism §1). To interpret mathematical geometry for application to physical space we must of course adopt certain conventions, such as deciding that a certain type of measuring instrument retains its length unchanged as it is transported from place to place. By calling such decisions 'coordinative definitions' he emphasized their status as conventions. Once such a decision is made, however, the structure of physical space becomes a matter of empirical fact. A different choice of a coordinative definition, employed in the same space, may yield a different geometry, but the descriptions based on these different coordinative definitions are physically equivalent. According to Reichenbach's 'theory of equivalent descriptions', then, one set of equivalent descriptions (rather than a single description) correctly describes physical space, but other logically possible sets of equivalent descriptions give false descriptions of physical space (see Geometry, philosophical issues in).

On one aspect of time, Reichenbach took a more strongly conventionalistic position. According to special relativity, no signal can travel faster than light *in vacuo*. The fact that this speed is finite places limits on our ability to synchronize clocks located at different places in any inertial frame of reference. Given two spatially separated clocks *A* and *B*, if we send a light signal at t_1 from *A* to *B* where it is reflected back to *A*, arriving at t_3, then we can choose any time t_2 between t_1 and t_3 as its time of arrival at *B*. This amounts to saying that, while the round-trip speed of light is a matter of physical fact, the one-way speed of light is (within limits) a matter of convention. An important result by David Malament (1977) indicates that causal constraints imply that the two one-way speeds are equal (see Relativity theory, philosophical significance of §3).

One of Reichenbach's fundamental purposes in developing his theories of space and time was to implement a causal theory. He believed that causal processes, such as light pulses and moving material objects, as well as causal interactions, such as reflections of light pulses by mirrors or collisions of material particles, constitute verifiable features of the world, whereas the abstract structure of spacetime by itself does not. In his posthumously published work, *The Direction of Time* (1956), Reichenbach seeks to ground the direction of time - the difference between past and future - in causal aspects of the universe that are also probabilistic. This book contains pioneering work on the concept of probabilistic causality.

5 Other topics

Reichenbach also made significant contributions to other subjects. A major scientific revolution of the twentieth century was the advent of quantum mechanics. Reichenbach's book on this development, *Philosophic Foundations of Quantum Mechanics* (1944), emphasizes causal anomalies, and introduces a three-valued logic (in which a statement can have the value indeterminate as well as true or false) to deal with these problems (see Many-valued logics; Quantum logic; Quantum mechanics, interpretation of §3). Additional discussions of quantum mechanics

are included in *The Direction of Time*.

Reichenbach's *Elements of Symbolic Logic* (1947), his major work on symbolic logic, contains an extended analysis of conversational language, as well as an analysis of laws of nature, physical modalities (necessity, possibility and impossibility) and counterfactual conditionals (see Laws, natural §2; Counterfactual conditionals). These three topics receive a fuller treatment in his monograph, *Nomological Statements and Admissible Operations* (1954).

Although he never wrote a book on the subject, discussions of causality can be found in his writings throughout his career. He wrote very little explicitly on the nature of scientific explanation, but his work on causality contains many valuable hints (see Explanation §4).

Finally, on the basis of his verifiability criterion of meaning, Reichenbach adopted a non-cognitivist ethical theory in *The Rise of Scientific Philosophy* (1951). For him, ethical utterances were expressions of 'volitional decisions'. Fundamental value judgments cannot be considered true or false, but scientific knowledge and logic are extremely useful in dealing with 'entailed decisions', that is, hypothetical value judgments about the compatibility or incompatibility of various basic value judgments and about the selection of appropriate means to reach desired ends.

List of works

Reichenbach, H. (1977-) *Hans Reichenbach: Gesammelte Werke in 9 Bänden (Hans Reichenbach: Collected Works in Nine Volumes)*, ed. A. Kamlah and M. Reichenbach, Wiesbaden: Friedr. Vieweg and Sohn.(All works appear in German, including those originally written or published in other languages.)

Reichenbach, H. (1978) *Hans Reichenbach: Selected Writings, 1909-1953*, ed. R. Cohen and M. Reichenbach, Dordrecht: Reidel.(All works appear in English; contains an excellent bibliography of Reichenbach's writings.)

Reichenbach, H. (1916) 'Der Begriff der Wahrscheinlichkeit für die mathematische Darstellung der Wirklichkeit' (The Concept of Probability for the Mathematical Representation of Reality), *Zeitschrift für Philosophie und philosophische Kritik* 161: 210-39; 162: 98-112, 223-53.(A reprint of Reichenbach's doctoral dissertation.)

Reichenbach, H. (1920) *Relativitätstheorie und Erkenntnis Apriori*, Berlin: Springer; trans. M. Reichenbach, *The Theory of Relativity and A Priori Knowledge*, Berkeley and Los Angeles, CA: University of California Press, 1965.(Reichenbach's first major challenge to Kant's theory of space and time. Translation contains a comprehensive introductory essay on Reichenbach's philosophy of space and time by M. Reichenbach.)

Reichenbach, H. (1924) *Axiomatik der Relativistischen Raum-Zeit-Lehre*, Braunschweig: Vieweg; trans. M. Reichenbach, *Axiomatization of the Theory of Relativity*, Berkeley and Los Angeles, CA: University of California Press, 1969.(A rather technical work in which Reichenbach attempts to clarify logical features of Einstein's theories by means of an axiomatic approach.)

Reichenbach, H. (1928) *Philosophie der Raum-Zeit-Lehre*, Berlin and Leipzig: de Gruyter; trans. M. Reichenbach, *The Philosophy of Space and Time*, New York: Dover, 1957.(*The* central classic in twentieth-century philosophy of space and time.)

Reichenbach, H. (1933) 'Rudolf Carnap, Der logische Aufbau der Welt' (Rudolf Carnap's The Logical Structure of the World), *Kantstudien* 38: 199-201.(A review of Carnap's *Aufbau* (1928), and Reichenbach's first challenge to logical positivism; it is fully developed in Reichenbach (1938).)

Reichenbach, H. (1935) *Wahrscheinlichkeitslehre (Theory of Probability)*, Leiden: A.W. Sijthoff's Uitgeversmattschappij; 2nd enlarged edn, trans. E.H. Hutton and M. Reichenbach, *The Theory of Probability*, Berkeley and Los Angeles, CA: University of California Press, 1949.(Reichenbach's major treatise on probability and induction.)

Reichenbach, H. (1938) *Experience and Prediction*, Chicago, IL: University of Chicago Press. (Reichenbach's treatise on epistemology, containing his refutation of logical positivism.)

Reichenbach, H. (1944) *Philosophic Foundations of Quantum Mechanics*, Berkeley and Los Angeles, CA: University of California Press.(Reichenbach's attempt to resolve problems of quantum mechanics using the nonstandard (3-valued) logic.)

Reichenbach, H. (1947) *Elements of Symbolic Logic*, New York: Macmillan.(Reichenbach's analysis of conversational language (including verb tenses) in chapter 7 is especially interesting.)

Reichenbach, H. (1951) *The Rise of Scientific Philosophy*, Berkeley and Los Angeles, CA: University of California Press.(Reichenbach's popularized account of his philosophy.)

Reichenbach, H. (1954) *Nomological Statements and Admissible Operations*, Amsterdam: North-Holland. (Reissued in 1976 (see below) and with a new foreword; the title later describes the topics covered in this work.)

Reichenbach, H. (1956) *The Direction of Time*, Berkeley and Los Angeles: University of California Press. (Contains many valuable ideas concerning causality and explanation, along with important approaches to problems of temporal symmetry.)

Reichenbach, H. (1976) *Laws, Modalities, and Counterfactuals*, Berkeley and Los Angeles, CA: University of California Press.(The new foreword attempts to make Reichenbach's convoluted theory accessible to a wide audience of philosophers.)

Reid, Thomas (1710-1796)

Thomas Reid, born at Strachan, Aberdeen, was the founder of the Scottish school of Common Sense philosophy. Educated at Marishal College, Aberdeen, he taught at King's College, Aberdeen until appointed professor of moral philosophy at Glasgow. He was the co-founder of the Aberdeen Philosophical Society or 'Wise Club', which counted among its members George Campbell, John Stewart, Alexander Gerard and James Beattie. His most noteworthy early work, An Inquiry into the Human Mind: Or the Principles of Common Sense attracted the attention of David Hume and secured him his professorship. Other important works are Essays on the Intellectual Powers of Man (1785) and Essays on the Active Powers of the Human Mind (1788).

Reid is not the first philosopher to appeal to common sense; Berkeley and Butler are notable British predecessors in this respect, in the discussions of perception and of free will respectively. It fell to Reid, however, to collect and systematize the deliverances of common sense - the first principles, upon the acceptance of which all justification depends - and to provide adequate criteria for that status. Reid insists we rightly rely on our admittedly fallible faculties of judgment, including the five senses, as well as memory, reason, the moral sense and taste, without need of justification. After all, we have no other resources for making judgments, to call upon in justification of this reliance. We cannot dispense with our belief that we are continually existing and sometimes fully responsible agents, influenced by motives rather than overwhelmed by passions or appetites. In Reid's view major sceptical errors in philosophy arise from downgrading the five senses to mere inlets for mental images - ideas - of external objects, and from downgrading other faculties to mere capacities for having such images or for experiencing feelings. This variety of scepticism ultimately reduces everything to a swirl of mental images and feelings. However we no more conceive such images than perceive or remember them; and our discourse, even in the case of fiction, is not about them either. Names signify individuals or fictional characters rather than images of them; when I envisage a centaur it is an animal I envisage rather than the image of an animal. In particular the information our five senses provide in a direct or non-inferential manner is, certainly in the case of touch, about bodies in space.

Reid thus seems to be committed to the position that our individual perceptual judgments are first principles in spite of his admission that our perceptual faculties are fallible. Moreover, moral and aesthetic judgments cannot be mere expressions of feeling if they are to serve their purposes; a moral assessor is not a 'feeler'. Reid is therefore sure that there are first principles of morals, a view that scarcely fits the extent and degree of actual moral disagreement.
